

## Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32H7x3 microcontroller memory and peripherals.

The STM32H7x3 is a line of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics please refer to the corresponding datasheets.

For information on the ARM<sup>®</sup> Cortex<sup>®</sup>-M7 with FPU cores, please refer to the corresponding ARM *Technical Reference Manuals*.

**56 FD Controller Area Network (FDCAN) ..... 2367**

56.1 Introduction ..... 2367

56.2 FDCAN main features ..... 2370

56.3 FDCAN functional description ..... 2371

56.3.1 Operating modes ..... 2372

56.3.2 Message RAM ..... 2381

56.3.3 FIFO acknowledge handling ..... 2392

56.3.4 Clock calibration on CAN ..... 2393

56.3.5 TTCAN operations (FDCAN1 only) ..... 2397

56.3.6 TTCAN configuration ..... 2399

56.3.7 Message scheduling ..... 2401

56.3.8 TTCAN gap control ..... 2408

56.3.9 Stop watch ..... 2408

56.3.10 Local time, cycle time, global time,  
and external clock synchronization ..... 2409

56.3.11 TTCAN error level ..... 2412

56.3.12 TTCAN message handling ..... 2413

56.3.13 TTCAN interrupt and error handling ..... 2416

56.3.14 Level 0 ..... 2416

56.3.15 Synchronization to external time schedule ..... 2419

56.3.16 FDCAN Rx Buffer and FIFO element ..... 2420

56.3.17 FDCAN Tx Buffer element ..... 2422

56.3.18 FDCAN Tx Event FIFO element ..... 2424

56.3.19 FDCAN Standard message ID Filter element ..... 2425

56.3.20 FDCAN Extended message ID filter element ..... 2427

56.3.21 FDCAN Trigger memory element ..... 2428

56.4 FDCAN registers ..... 2431

56.4.1 FDCAN Core Release Register (FDCAN\_CREL) ..... 2431

56.4.2 FDCAN Core Release Register (FDCAN\_ENDN) ..... 2431

56.4.3 FDCAN Data Bit Timing and Prescaler Register (FDCAN\_DBTP) .. 2432

56.4.4 FDCAN Test Register (FDCAN\_TEST) ..... 2433

56.4.5 FDCAN RAM Watchdog Register (FDCAN\_RWD) ..... 2433

56.4.6 FDCAN CC Control Register (FDCAN\_CCCR) ..... 2434

56.4.7 FDCAN Nominal Bit Timing and Prescaler Register  
(FDCAN\_NBTP) ..... 2436

56.4.8 FDCAN Timestamp Counter Configuration Register (FDCAN\_TSCC) ..... 2437

56.4.9 FDCAN Timestamp Counter Value Register (FDCAN\_TSCV) ..... 2438

56.4.10 FDCAN Timeout Counter Configuration Register (FDCAN\_TOCC) . 2439

56.4.11 FDCAN Timeout Counter Value Register (FDCAN\_TOCV) ..... 2439

56.4.12 FDCAN Error Counter Register (FDCAN\_ECR) ..... 2440

56.4.13 FDCAN Protocol Status Register (FDCAN\_PSR) ..... 2441

56.4.14 FDCAN Transmitter Delay Compensation Register (FDCAN\_TDCR) 2443

56.4.15 FDCAN Interrupt Register (FDCAN\_IR) ..... 2443

56.4.16 FDCAN Interrupt Enable Register (FDCAN\_IE) ..... 2446

56.4.17 FDCAN Interrupt Line Select Register (FDCAN\_ILS) ..... 2449

56.4.18 FDCAN Interrupt Line Enable Register (FDCAN\_ILE) ..... 2450

56.4.19 FDCAN Global Filter Configuration Register (FDCAN\_GFC) ..... 2451

56.4.20 FDCAN Standard ID Filter Configuration Register (FDCAN\_SIDFC) 2452

56.4.21 FDCAN Extended ID Filter Configuration Register (FDCAN\_XIDFC) 2452

56.4.22 FDCAN Extended ID and Mask Register (FDCAN\_XIDAM) ..... 2453

56.4.23 FDCAN High Priority Message Status Register (FDCAN\_HPMS) ... 2454

56.4.24 FDCAN New Data 1 Register (FDCAN\_NDAT1) ..... 2454

56.4.25 FDCAN New Data 2 Register (FDCAN\_NDAT2) ..... 2455

56.4.26 FDCAN Rx FIFO 0 Configuration Register (FDCAN\_RXF0C) ..... 2455

56.4.27 FDCAN Rx FIFO 0 Status Register (FDCAN\_RXF0S) ..... 2456

56.4.28 CAN Rx FIFO 0 Acknowledge Register (FDCAN\_RXF0A) ..... 2457

56.4.29 FDCAN Rx Buffer Configuration Register (FDCAN\_RXBC) ..... 2457

56.4.30 FDCAN Rx FIFO 1 Configuration Register (FDCAN\_RXF1C) ..... 2458

56.4.31 FDCAN Rx FIFO 1 Status Register (FDCAN\_RXF1S) ..... 2459

56.4.32 FDCAN Rx FIFO 1 Acknowledge Register (FDCAN\_RXF1A) ..... 2460

56.4.33 FDCAN Rx Buffer Element Size Configuration Register (FDCAN\_RXESC) ..... 2460

56.4.34 FDCAN Tx Buffer Configuration Register (FDCAN\_TXBC) ..... 2461

56.4.35 FDCAN Tx FIFO/Queue Status Register (FDCAN\_TXFQS) ..... 2462

56.4.36 FDCAN Tx Buffer Element Size Configuration Register (FDCAN\_TXESC) ..... 2463

56.4.37 FDCAN Tx Buffer Request Pending Register (FDCAN\_TXBRP) ... 2464

56.4.38 FDCAN Tx Buffer Add Request Register (FDCAN\_TXBAR) ..... 2465

56.4.39 FDCAN Tx Buffer Cancellation Request Register (FDCAN\_TXBCR) 2465

56.4.40 FDCAN Tx Buffer Transmission Occurred Register (FDCAN\_TXBTO) ..... 2466

56.4.41 FDCAN Tx Buffer Cancellation Finished Register (FDCAN\_TXBCF) 2466

# 1 Documentation conventions

## 1.1 List of abbreviations for registers

The following abbreviations are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear (rc_w1)	Software can read as well as clear this bit by writing 1. Writing '0' has no effect on the bit value.
read/clear (rc_w0)	Software can read as well as clear this bit by writing 0. Writing '1' has no effect on the bit value.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to '0'. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing '0' has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

## 1.2 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word:** data of 32-bit length.
- **Half-word:** data of 16-bit length.
- **Byte:** data of 8-bit length.
- **Double word:** data of 64-bit length.
- **Flash word:** data of 256-bit length
- **IAP (in-application programming):** IAP is the ability to re-program the Flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming):** ICP is the ability to program the Flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes:** product configuration bits stored in the Flash memory.
- **AHB:** advanced high-performance bus.
- **AXI:** Advanced extensible Interface protocol
- **PCROP:** proprietary code readout protection.
- **RDP:** readout protection

## 1.3 Peripheral availability

For peripheral availability and number across all sales types, refer to the particular device datasheet.

## 2 Memory and bus architecture

### 2.1 System architecture

An AXI bus matrix, two AHB bus matrices and bus bridges allow interconnecting bus masters with bus slaves, as illustrated in [Table 1](#) and [Figure 1](#).

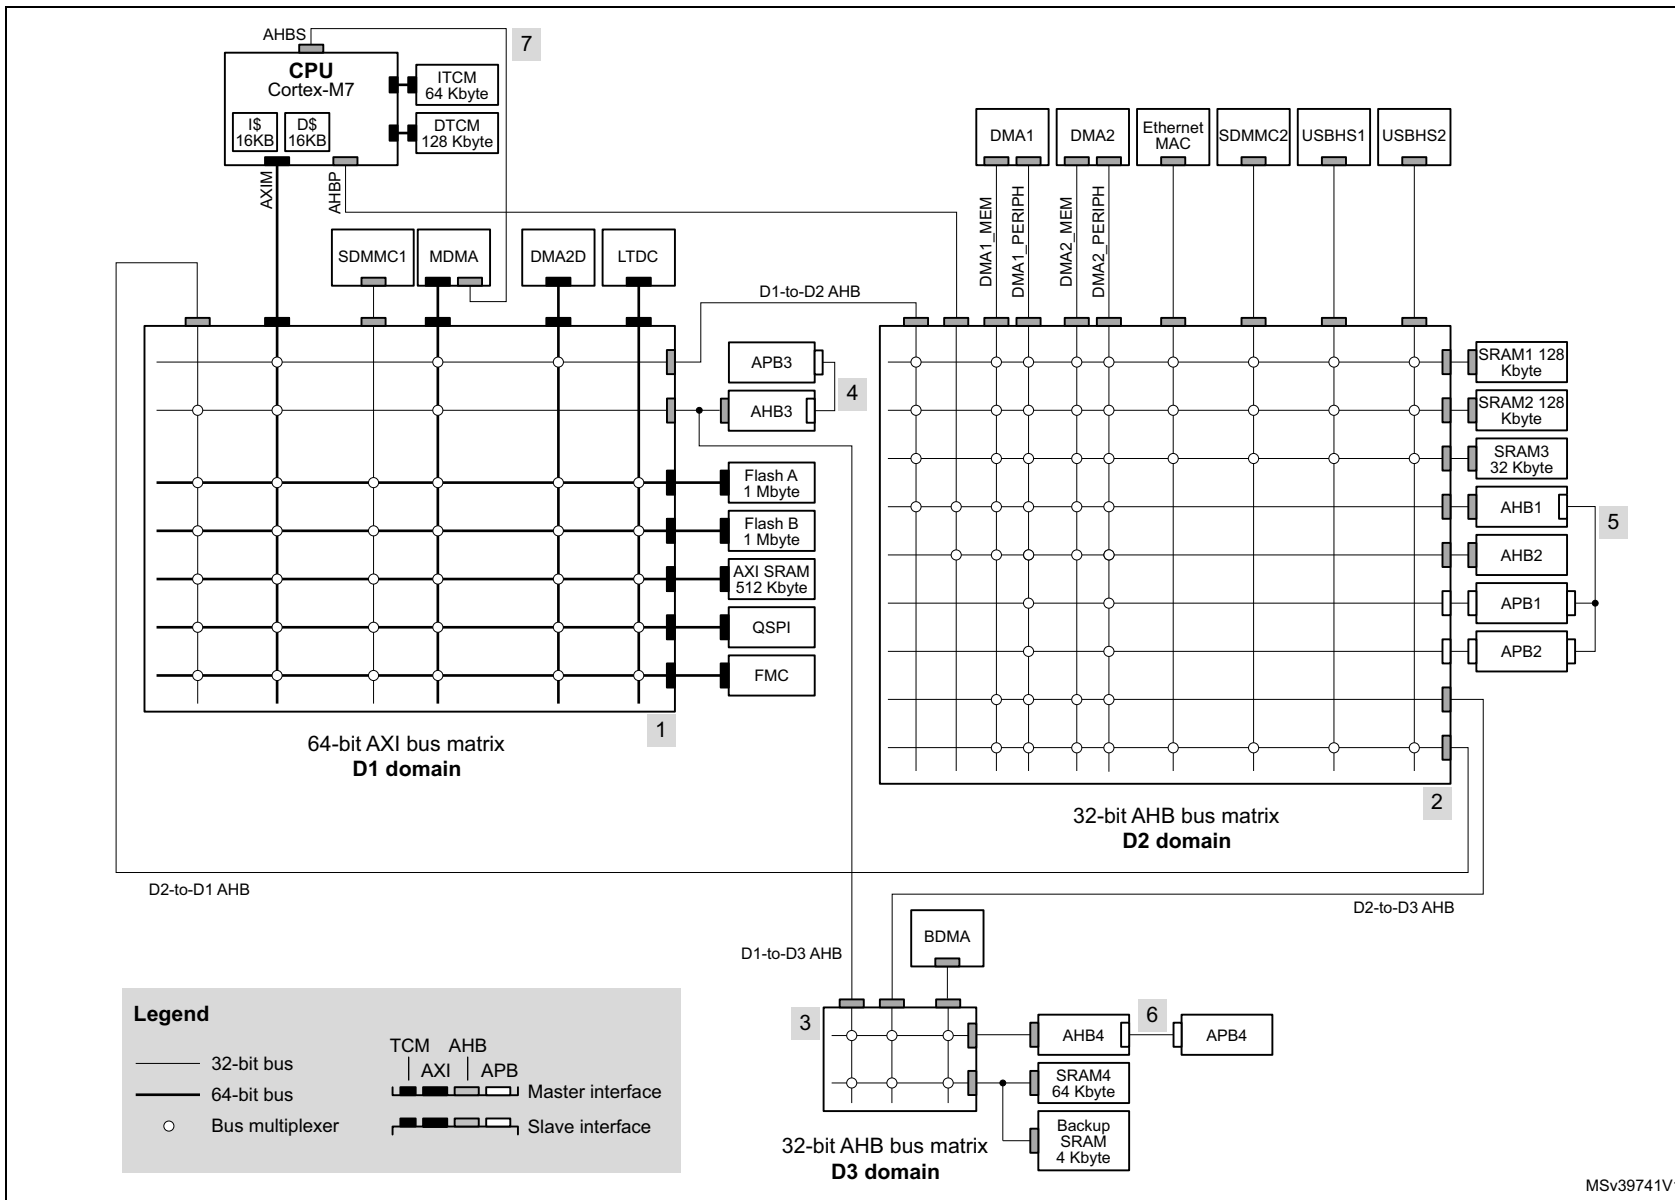

**Table 1. Bus-master-to-bus-slave interconnect**

Bus slave / type <sup>(1)</sup>	Bus master / type <sup>(1)</sup>

- Bold** font type denotes 64-bit bus, plain type denotes 32-bit bus.
- Cells in the table body indicate access possibility, utility, path and type:  
Access possibility and utility:  
 Any figure = access possible, "-" = access not possible, shading = access useful/usable  
Access path:  
 D=direct, 1=via AXI bus matrix, 2=via AHB bus matrix in D2, 3=via AHB bus matrix in D3, 4=via AHB/APB bridge in D1, 5=via AHB/APB bridge in D2, 6=via AHB/APB bridge in D3, 7=via AHBS bus of Cortex-M7,  
 Multi-digit numbers = interconnect path goes through more than one matrix or/and bridge, in the order of the digits.  
Access type:  
 Plain=32-bit, *Italic*=32-bit on bus master end / 64-bit on bus slave end, **Bold**=64-bit

## 2.1.1 Bus matrices

### AXI bus matrix in D1 domain

The D1 domain multi AXI bus matrix ensures and arbitrates concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm with QoS capability.

The DTCM and ITCM (data and instruction tightly coupled RAMs) are connected through dedicated TCM buses directly to the Cortex-M7 core. The MDMA controller can access the DTCM and ITCM through AHBS, a specific CPU slave AHB. The ITCM is accessed by Cortex-M7 at CPU clock speed, with zero wait states.

Refer to [Section 5: AXI interconnect](#) for more information on AXI interconnect.

### AHB bus matrices in D2 and D3 domains

The AHB bus matrices in D2 and D3 domains ensure and arbitrate concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm.

## 2.1.2 Bus-to-bus bridges

To allow peripherals with different types of buses to communicate together, there is a number of bus-to-bus bridges in the system.

The AHB/APB bridges in D1 and D3 domains allow connecting peripherals on APB3 and APB4 to AHB3 and AHB4, respectively. The AHB/APB bridges in D2 domain allow peripherals on APB1 and APB2 to connect to AHB1. These AHB/APB bridges provide full synchronous interfacing, which allows the APB peripherals to operate with clocks independent of AHB that they connect to.

The AHB/APB bridges also allow APB1 and APB2 peripherals to connect to DMA1 and DMA2 peripheral buses, respectively, without transiting through AHB1.

The AHB/APB bridges convert 8-bit / 16-bit APB data to 32-bit AHB data, by replicating it to the three upper bytes / the upper half-word of the 32-bit word.

The AXI bus matrix incorporates AHB/AXI bus bridge functionality on its slave bus interfaces. The AXI/AHB bus bridges on its master interfaces marked as 32-bit in [Figure 1](#) are outside the matrix.

The Cortex-M7 CPU provides AHB/TCM-bus (ITCM and DTCM buses) translation from its AHBS slave AHB, allowing the MDMA controller to access the ITCM and DTCM.

## 2.1.3 Inter-domain buses

### D2-to-D1 AHB

This 32-bit bus connects the D2 domain to the AXI bus matrix in the D1 domain. It allows bus masters in the D2 domain to access resources (bus slaves) in the D1 domain and indirectly, via the D1-to-D3 AHB, in the D3 domain.

### **D1-to-D2 AHB**

This 32-bit bus connects the D1 domain to the D2 domain AHB bus matrix. It allows bus masters in the D1 domain to access resources (bus slaves) in the D2 domain.

### **D1-to-D3 AHB**

This 32-bit bus connects the D1 domain to the D3 domain AHB bus matrix. It allows bus masters in the D1 domain to access resources (bus slaves) in the D3 domain.

### **D2-to-D3 AHB**

This 32-bit bus connects the D2 domain to the D3 domain AHB bus matrix. It allows bus masters in the D2 domain to access resources (bus slaves) in the D3 domain.

## **2.1.4 CPU buses**

### **Cortex<sup>®</sup>-M7 AXIM bus**

The Cortex<sup>®</sup>-M7 CPU uses the 64-bit AXIM bus for accesses with all memories and peripherals excluding the ITCM, DTCM, AHB2 peripherals, and, due to addressing incompatibility, excluding also the AHB1, APB1 and APB2 peripherals.

The AXIM bus connects the CPU to the AXI bus matrix in the D1 domain.

### **Cortex<sup>®</sup>-M7 ITCM bus**

The Cortex<sup>®</sup>-M7 CPU uses the 64-bit ITCM bus for fetching instructions from and accessing data in the ITCM.

### **Cortex<sup>®</sup>-M7 DTCM bus**

The Cortex<sup>®</sup>-M7 CPU uses the 64-bit DTCM bus for accessing data in the DTCM. It can also fetch instructions.

### **Cortex<sup>®</sup>-M7 AHBS bus**

The Cortex<sup>®</sup>-M7 CPU uses the 32-bit AHBS slave bus to allow the MDMA controller to access the ITCM and the DTCM.

### **Cortex<sup>®</sup>-M7 AHBP bus**

The Cortex<sup>®</sup>-M7 CPU uses the 32-bit AHBP bus for accessing AHB1, AHB2, APB1 and APB2 peripherals via the AHB bus matrix in the D2 domain.

## **2.1.5 Bus master peripherals**

### **SDMMC1**

The SDMMC1 uses a 32-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and Flash memories, and external memories through the Quad-SPI controller and the FMC.

## **SDMMC2**

The SDMMC2 uses a 32-bit bus, connected to the AHB bus matrix in D2 domain. Through the system bus matrices, it can access the internal AXI SRAM, SRAM1, SRAM2, SRAM3 and Flash memories, and external memories through the Quad-SPI controller and the FMC.

## **MDMA controller**

The MDMA controller uses a 64-bit bus, connected to the AXI bus matrix, for DMA data transfers between memories and with peripherals. Through the system bus matrices and the Cortex-M7 AHBS slave bus, it can access all internal memories and AHB1 peripherals. It can also access external memories through the Quad-SPI controller and the FMC.

## **DMA1 and DMA2 controllers**

The DMA1 and DMA2 controllers have two 32-bit buses - memory bus and peripheral bus, connected to the AHB bus matrix in D2 domain.

The memory bus allows DMA data transfers between memories. Through the system bus matrices, the memory bus can access all internal memories except ITCM and DTCM, and external memories through the Quad-SPI controller and the FMC.

The peripheral bus allows DMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through the system bus matrices, the peripheral bus can access all internal memories except ITCM and DTCM, external memories through the Quad-SPI controller and the FMC, and all AHB and APB peripherals. A direct access to APB1 and APB2 is available, without passing through AHB1.

## **BDMA controller**

The BDMA controller uses a 32-bit bus, connected to the AHB bus matrix in D3 domain, for DMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through the AHB bus matrix in the D3 domain, it can access the internal SRAM4, backup RAM, and AHB4 and APB4 peripherals.

## **Chrom-Art Accelerator™ (DMA2D)**

The DMA2D graphics accelerator uses a 64-bit bus, connected to the AXI bus matrix. Through the system bus matrices, internal AXI SRAM, SRAM1, SRAM2, SRAM3 and Flash memories, and external memories through the Quad-SPI controller and the FMC.

## **LCD-TFT controller (LTDC)**

The LCD-TFT display controller, LTDC, uses a 64-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and Flash memories, and external memories through the Quad-SPI controller and the FMC.

## **Ethernet MAC**

The Ethernet MAC uses a 32-bit bus, connected to the AHB bus matrix in the D2 domain. Through the system bus matrices, it can access all internal memories except ITCM and DTCM, and external memories through the Quad-SPI controller and the FMC.

### **USBHS1 and USBHS2 peripherals**

The USBHS1 and USBHS2 peripherals use 32-bit buses, connected to the AHB bus matrix in the D2 domain. Through the system bus matrices, they can access all internal memories except ITCM and DTCM, and external memories through the Quad-SPI controller and the FMC.

#### **2.1.6 Clocks to functional blocks**

Upon reset, clocks to blocks such as peripherals and some memories are disabled (except for the SRAM, DTCM, ITCM and Flash memory). To operate a block with no clock upon reset, the software must first enable its clock through `RCC_AHBxENR` or `RCC_APBxENR` register, respectively.

## 2.2 Memory organization

### 2.2.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into 8 main blocks, of 512 Mbytes each.

All the memory map areas that are not allocated to on-chip memories and peripherals are considered "Reserved". For the detailed mapping of available memory and register areas, refer to [Memory map and register boundary addresses](#) and peripheral sections.

### 2.2.2 Memory map and register boundary addresses

See the datasheet corresponding to your device for a comprehensive diagram of the memory map.

The following table gives the boundary addresses of the peripherals available in the devices.

**Table 2. Register boundary addresses**

Boundary address	Peripheral	Bus	Register map
0x58026400 - 0x580267FF	HSEM	AHB4 (D3)	<a href="#">Section 10.4: HSEM registers</a>

## 2.3 Embedded SRAM

The STM32H7x3 devices feature:

- Up to 864 Kbytes of System SRAM
- 128 Kbytes of data TCM RAM
- 64 Kbytes of instruction TCM RAM
- 4 Kbytes of backup SRAM

The embedded system SRAM is divided into up to five blocks:

- AXI SRAM (D1 domain):
  - AXI SRAM mapped at address 0x2400 0000 and accessible by all system masters except BDMA through D1 domain AXI bus matrix
- AHB SRAM (D2 domain):
  - AHB SRAM1 mapped at address 0x3000 0000 and accessible by all system masters except BDMA through D2 domain AHB matrix
  - AHB SRAM2 mapped at address 0x3002 0000 and accessible by all system masters except BDMA through D2 domain AHB matrix
  - AHB SRAM3 mapped at address 0x3004 0000 and accessible by all system masters except BDMA through D2 domain AHB matrix
- AHB SRAM (D3 domain):
  - AHB SRAM4 mapped at address 0x3800 0000 and accessible by most of system masters through D3 domain AHB matrix

The system AHB SRAM can be accessed as bytes, half-words (16-bit units) or full-words (32-bit units), while the system AXI SRAM can be accessed as bytes, half-words, full-words or double-words (64-bit units). These memories can be addressed at maximum system clock frequency without wait state.

The AHB masters can read/write-access an SRAM section concurrently with the Ethernet MAC or the USB OTG HS peripheral accessing another SRAM section. For example, the Ethernet MAC accesses the SRAM2 while the CPU accesses the SRAM1, concurrently.

The TCM SRAMs are dedicated to the Cortex<sup>®</sup>-M7:

- DTCM-RAM on TCM interface is mapped at the address 0x2000 0000 and accessible by Cortex<sup>®</sup>-M7, and by MDMA through AHBS slave bus of the Cortex<sup>®</sup>-M7 CPU.
- ITCM-RAM on TCM interface mapped at the address 0x0000 0000 and accessible by Cortex<sup>®</sup>-M7 and by MDMA through AHBS slave bus of the Cortex<sup>®</sup>-M7 CPU.

The backup RAM is mapped at the address 0x3880 0000 and is accessible by most of the system masters through D3 domain's AHB matrix.

## 2.4 Flash memory overview

The Flash memory interface manages CPU AXI accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory is organized as follows:

- Two main memory block divided into sectors.
- An information block:
  - System memory from which the device boots in System memory boot mode
  - Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to [Section 3: Embedded Flash memory \(FLASH\)](#) for more details.

## 2.5 Boot configuration

In the STM32H7x3, two different boot areas can be selected through the BOOT pin and the boot base address programmed in the BOOT\_ADD0 and BOOT\_ADD1 option bytes as shown in the [Table 3](#).

**Table 3. Boot modes**

Boot mode selection		Boot area
BOOT	Boot address option bytes	
0	BOOT_ADD0[15:0]	Boot address defined by user option byte BOOT_ADD0[15:0] ST programmed value: Flash memory at 0x0800 0000
1	BOOT_ADD1[15:0]	Boot address defined by user option byte BOOT_ADD1[15:0] ST programmed value: System bootloader at 0x1FF0 0000

The values on the BOOT pin are latched on the 4th rising edge of SYSCCLK after reset release. It is up to the user to set the BOOT pin after reset.

The BOOT pin is also re-sampled when the device exits the Standby mode. Consequently, they must be kept in the required Boot mode configuration when the device is in the Standby mode.

After startup delay, the selection of the boot area is done before releasing the processor reset.

The BOOT\_ADD0 and BOOT\_ADD1 address option bytes allows to program any boot memory address from 0x0000 0000 to 0x3FFF 0000 which includes:

- All Flash address space
- All RAM address space: ITCM, DTCM RAMs and SRAMs
- The TCM-RAM

The BOOT\_ADD0 / BOOT\_ADD1 option bytes can be modified after reset in order to boot from any other boot address after next reset.

If the programmed boot memory address is out of the memory mapped area or a reserved area, the default boot fetch address is programmed as follows:

- Boot address 0: FLASH at 0x0800 0000
- Boot address 1: ITCM-RAM at 0x0000 0000

---

When the Flash level 2 protection is enabled, only boot from Flash memory is available. If the boot address already programmed in the BOOT\_ADD0 / BOOT\_ADD1 option bytes is out of the memory range or belongs to the RAM address range, the default fetch will be forced from Flash memory at address 0x0800 0000 .

### **Embedded bootloader**

The embedded bootloader code is located in system memory. It is programmed by ST during production. It is used to reprogram the Flash memory using one of the following serial interfaces:

- USART1 on pins PA9/PA10 and PB14/PB15, USART2 on pins PA3/PA2 and USART3 on pins PB10/PB11.
- I2C1 on pins PB6/PB9, I2C2 on pins PF0/PF1 and I2C3 on pins PA8/PC9
- USB OTG FS in Device mode (DFU) on pins PA11/PA12
- SPI1 on pins PA7/PA6/PA5/PA4, SPI2 on pins PI3/PI2/PI1/PI0, SPI3 on pins PC12/PC11/PC10/PA15 and SPI4 on pins PE14/PE13/PE12/PE11.

For additional information, refer to the application note AN2606.

## 3 Embedded Flash memory (FLASH)

### 3.1 Introduction

The Flash memory interface manages AXI accesses of any master to the Flash memory. It implements the read, program and erase Flash memory operations as well as the read and program/erase protection mechanisms.

The Flash interface also manages the option byte loading at reset and the dynamic option byte change.

### 3.2 FLASH main features

- Memory density up to 2 Mbytes
- Error Code Correction (ECC): 10 ECC bits by 256-bit Flash word
- Double-word, word, half-word and byte read operations
- Flash programming by 256 bits
- Double-word, word, half-word and byte write operations
- Sector erase, Bank erase and Mass erase
- Dual-bank organization supporting simultaneous operations: two read/program/erase operations can be executed in parallel on the two banks
- Bank swapping: the address mapping of the user Flash memory of each bank can be swapped.
- Enhanced security features
  - Readout protection (RDP)
  - Sector write protection
  - 2 PCROP protection area (1 per bank) (execute-only memory)
- 2 secure area in user Flash memory (1 per bank)

### 3.3 FLASH functional description

#### 3.3.1 Block diagram

#### 3.3.2 Pins and internal signals

[Table 4](#) lists the FLASH inputs and output signals connected to package pins or balls, while [Table 5](#) shows the internal FLASH signals.

**Table 4. FLASH input/output signals connected to package pins or balls**

Signal name	Signal type	Description
NRST	Digital input	External reset signal.

**Table 5. FLASH internal input/output signals**

Signal name	Signal type	Description
sys_ck	Digital input	System clock
flash_it	Digital output	Embedded Flash memory interrupt

### 3.3.3 Flash memory architecture

The Flash memory is organized as 266-bit Flash words memory that can be used for storing both code and data constants. Each word consists of:

- One Flash word (8 words, 32 bytes or 256 bits)
- 10 ECC bits.

The Flash memory is divided into two independent banks. Each bank is organized as follows:

- A 1 Mbyte user Flash memory block containing eight user sectors of 128 Kbytes(4 K Flash words)
- 128 Kbytes of System Flash memory from which the device can boot:  
 This area contains root secure services (RSS) and the bootloader, which are used respectively for secure or non-secure Flash memory programming through one of the following interfaces: USART, USB (DFU), I2C, SPI or Ethernet. The System Flash memory is reserved for use by STMicroelectronics. It is programmed by STMicroelectronics when the device is manufactured, and then protected against spurious program/erase operations. For further details, please refer to application note AN2606 “STM32 microcontroller System Flash memory boot mode” available from <http://www.st.com>.
- 2 Kbytes (64 Flash words) of user option bytes for user configuration:  
 This area is available only in bank 1. Unlike user Flash memory and System Flash memory, it is not mapped to any memory address and can be accessed only through the Flash register interface.

*Figure 2* shows the Flash memory high-level block diagram while *Table 6* describes the Flash memory organization.

*Figure 3* gives an overview of the Flash memory mapping as well as of the protection mechanisms. A PCROP and a secure area can be defined for each bank. The properties of these protected areas are detailed in *Section 3.3.12: Protection mechanisms*, while the secure services stored in System Flash memory are described in *Section 4: Security memory management*.

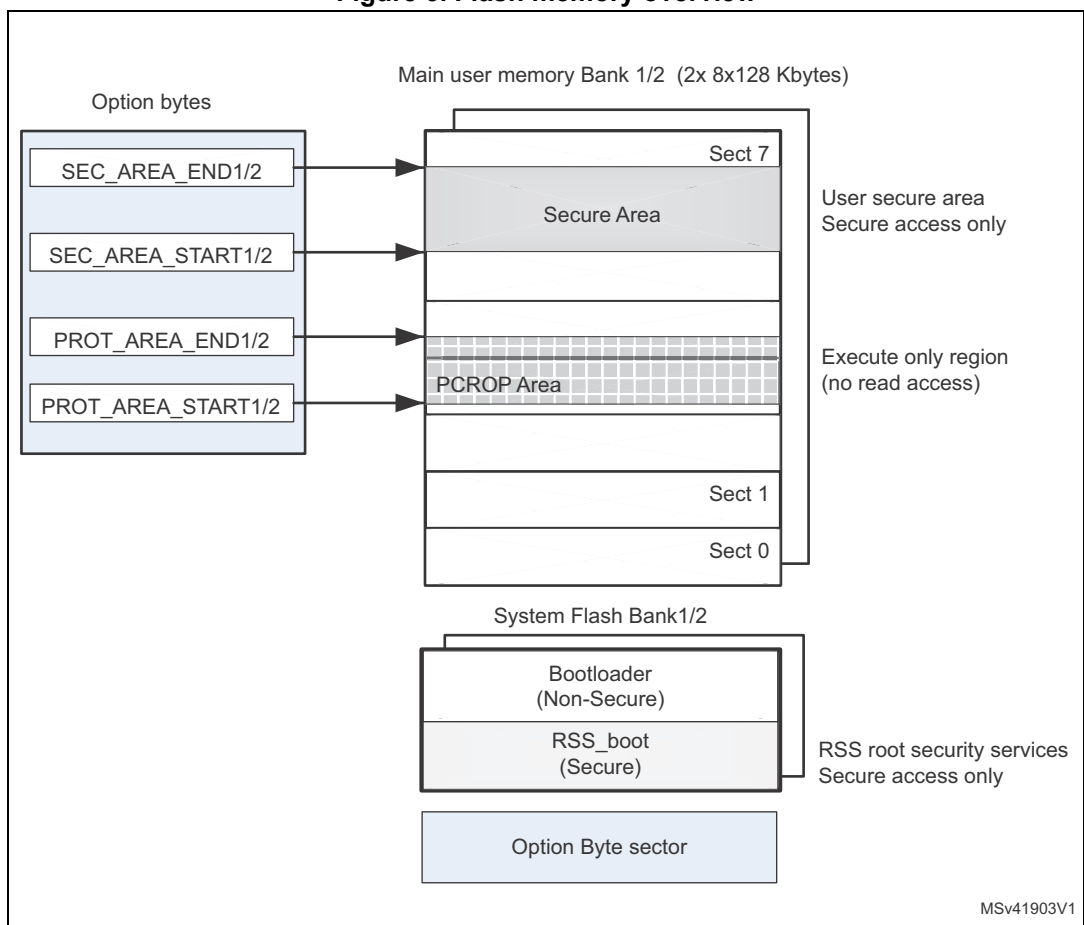

**Table 6. Flash module - 1 Mbyte dual bank organization**

Flash area		Start address	End address	Size (bytes)	Region Name
Bank 1	User Flash memory	0x0800 0000	0x0801 FFFF	128 K	Sector 0
		0x0802 0000	0x0803 FFFF	128 K	Sector 1
		...	...	...	...
		0x080E 0000	0x080F FFFF	128 K	Sector 7
	System Flash memory	0x1FF0 0000	0x1FF1 FFFF	128 K	System Flash memory

Table 6. Flash module - 1 Mbyte dual bank organization (continued)

Flash area		Start address	End address	Size (bytes)	Region Name
Bank 2	User Flash memory	0x0810 0000	0x0811 FFFF	128 K	Sector 0
		0x0812 0000	0x0813 FFFF	128 K	Sector 1
		...	...	...	...
		0x081E 0000	0x081F FFFF	128 K	Sector 7
	System Flash memory	0x1FF4 0000	0x1FF5 FFFF	128 K	System Flash memory

Figure 3. Flash memory overview

MSv41903V1

### 3.3.4 Flash read operations

#### Read protocol

The Flash interface support the following access types:

- Double-word (64 bits)
- Single-word (32 bits)
- Half-word (16 bits)
- Byte (8 bits)

The Flash interface clock must be enabled and running when reading data from Flash memory. To ensure correct Flash interface read operation, the number of wait states (LATENCY) must be correctly configured in the FLASH\_ACR register according to the Flash memory interface frequency (see [Section : Read access latency](#)).

A wrong number of wait states may results in incorrect read values (e.g.when not enough wait states have been programmed) or to a long access time (e.g.when too many wait states have been programmed).

The operations are executed in the order in which they have been received by the Flash interface.

The Flash interface is built in such a way that only one read, program or erase operation can be executed at a time on a given bank. As an example, let us consider the case where the user Flash memories are swapped. The first AXI interface requests a read operation on bank 1 System Flash memory (ICP) while the second AXI interface requests a read or fetch operation on the user Flash memory of the same bank. In this case, a hardware arbitration occurs and both read requests are accepted, but they are served sequentially.

Simultaneous read/program/erase operations are supported if they target different banks. When a read operation is requested while a program/erase operation is ongoing on the same bank, the read command is buffered and is executed after the program/erase operation has completed. The system is not stalled unless the read command FIFO is full (3 read operations are already pending).

#### Read sequence

The Flash interface implements a dual AXI bus interface for code/data accesses and an AHB interface for Flash interface configuration. The AXI interfaces can request a read/program operation at the same time.

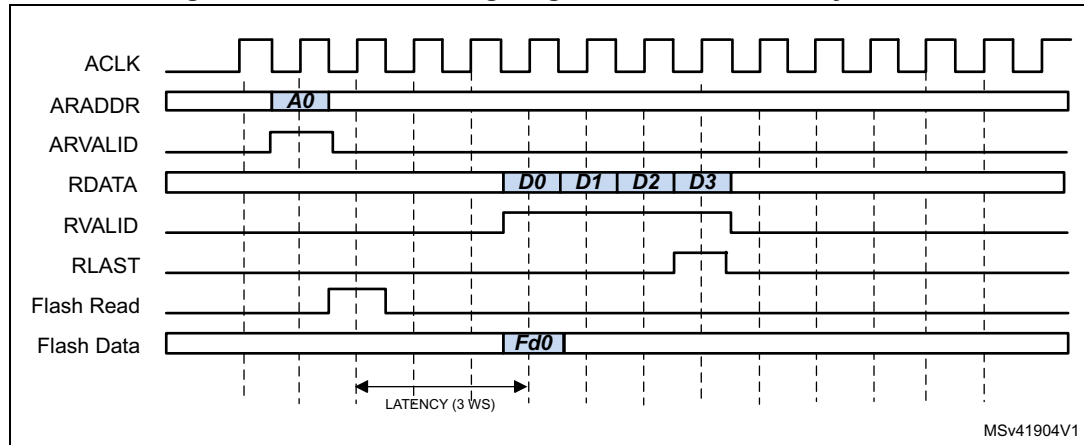

The read mechanism is the following:

- The read command buffer depth is fixed to 3 requests. When it is full (3 read requests queued in the buffer), any new read request will stall the bus interface and consequently the master.
- The Flash interface will free a request in the read command queue buffer as soon as the last data of current read transaction are transferred from the Flash memory to the read data buffer inside the Flash memory interface.
- Any system read request which data are not available in the read buffer will trigger a Flash read operation. This latter will be buffered inside the read data buffer.
- If several consecutive read accesses request data that belong to the same Flash data word (256 bits), data are read directly from the current data read buffer and do not trigger additional Flash read operations.

Figure 4 and Figure 5 show the timing diagrams of a burst read transaction of four and eight double-word data, respectively. The latency is configured to three wait states:

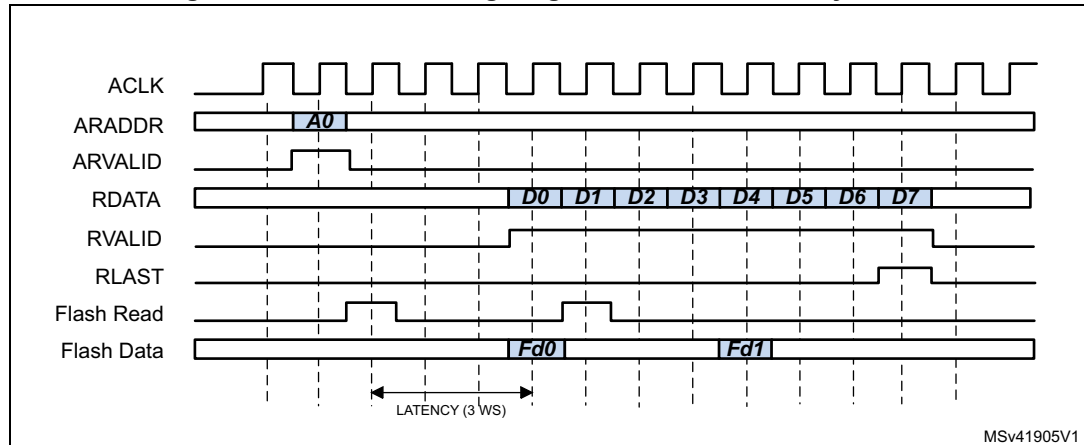

1. The first data are available after a first latency (three wait states).
2. Once the data are available in the read current buffer, the Flash interface is ready to execute the next command from the read command queue.
3. The second latency, corresponding to next Flash word read access, is masked by the current buffer read operation which can serve four double-word read consecutively. This is equivalent to a 0 wait-state execution sequence.

**Figure 4. Burst read timing diagram - 4x64bits, latency = 3 ws**

1. ACLK, ARADDR, ARVALID, RDATA, RVALID and RLAST are AXI bus signals. Flash Read and Flash Data are Flash interface signals.

**Figure 5. Burst read timing diagram - 8x64bits, latency = 3 ws**

1. ACLK, ARADDR, ARVALID, RDATA, RVALID and RLAST are AXI bus signals. Flash Read and Flash Data are Flash interface signals.

### Read access latency

To correctly read data from Flash memory, the number of wait states (LATENCY) must be correctly programmed in the Flash access control register (FLASH\_ACR) according to the frequency of the bus clock (aclk) and the internal voltage range of the device  $V_{CORE}$ .

[Table 7](#) shows the correspondence between the number of wait states, the bus clock frequency and  $V_{CORE}$  range.

**Table 7. Number of wait states according to bus frequency (ACLK) and  $V_{CORE}$  range**

$V_{CORE}$ range		Number of wait states	Maximum frequency
VOS1 level	1.15 V - 1.26 V	0	70 MHz
		1	140 MHz
		2	210 MHz
VOS2 level	1.05 V - 1.15 V	0	55 MHz
		1	110 MHz
		2	165 MHz
		3	220 MHz
VOS3 level	0.95 V - 1.05 V	0	45 MHz
		1	90 MHz
		2	135 MHz
		3	180 MHz
		4	225 MHz

After power-on, the clock used is the HSI (64 MHz) and 0x7 wait-states are configured by default in the FLASH\_ACR register. To change the bus frequency, the software sequences described in [Section : Adjusting the bus frequency](#) must be applied in order to tune the number of wait states required to access the Flash memory.

### Adjusting the bus frequency

- Increasing the bus frequency
  - a) If necessary, program the right number (see [Table 7](#)) of wait states to the LATENCY bits in the FLASH\_ACR register.
  - b) Check that the new number of wait states is taken into account to access the Flash memory by reading the FLASH\_ACR register.
  - c) Modify the Flash interface clock source and/or the bus clock prescaler in the RCC\_CFGR register.
  - d) Check that the new Flash interface clock source and/or the new Flash interface clock prescaler value has been taken in account, by reading the clock source status and/or the bus prescaler value, in the RCC\_CFGR register.
- Decreasing the bus frequency
  - a) Modify the Flash interface clock source and/or the bus clock prescaler in the RCC\_CFGR register.
  - b) Check that the new Flash interface clock source and/or the new bus clock prescaler value are taken into account by reading the Flash interface clock source status and/or the bus prescaler value in the RCC\_CFGR register.
  - c) If necessary, program the right number of wait states (see [Table 7](#)) to the LATENCY bits in FLASH\_ACR register.
  - d) Check that the new number of wait states has been taken into account by reading the FLASH\_ACR register.

### 3.3.5 Error code correction (ECC)

Data in Flash memory are 266-bit words: 10 ECC bits are added per Flash word of 256 bits. The ECC mechanism is based on the SECDED algorithm. It supports:

- Single error correction
- Double errors detection

When an error is detected and corrected, the SNECCERR1/2 flag is set in FLASH\_SR1/2 register. An interrupt is generated if SNECCERRIE bit is set in FLASH\_CR1/2 register.

When two errors are detected, the DBECCERR1/2 flag is set in FLASH\_SR1/2 register and a bus error is generated. In this case the received data are not corrected. An interrupt is generated if DBECCERRIE1/2 bit is set in FLASH\_CR1/2 register.

When an ECC error is detected, the address of the failing Flash word is saved in the FLASH\_ECC\_FA1/2R register. In case of successive error detections, only the address corresponding to the first error will be stored. This register is automatically cleared when the associated flag that generated the error has been reset.

### 3.3.6 Cyclic redundancy check module

The Flash interface embeds a cyclic redundancy check hardware module. This module allows checking the integrity of a Flash area content. This area can be defined either by sectors or by start/end addresses.

Only one CRC check operation on bank 1 or 2 can be launched at a time.

The CRC operation is concurrent with option byte change operations. This means that if a CRC operation is requested while an option byte change is ongoing, the option byte change operation must be complete before serving the CRC operation, and vice-versa.

When enabled, the CRC hardware module processes Flash data by chunks of 4, 16, 64 or 256 Flash words. CRC computation uses CRC-32 (Ethernet) polynomial  $0x4C11DB7$

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

The Flash interface internally issues 4, 16, 64 or 256 consecutive Flash-word read accesses. These transactions are queued into the read command queue together with other AXI read requests, thus avoiding to deny AXI read commands. The queue command buffer can contain only one CRC command.

The sequence recommended to configure a CRC operation in the bank 1/2 is the following:

1. Enable the CRC feature by setting the CRC\_EN bit in FLASH\_CR1/2.
2. Program the desired data size in the CRC\_BURST field of FLASH\_CRCCR1/2.
3. Define the Flash area on which the CRC has to be computed. Two solutions are possible:
  - Define the area start and end addresses by programming FLASH\_CRCSADD1/2R and FLASH\_CRCEADD1/2R, respectively
  - or select the targeted sectors by setting the CRC\_BY\_SECT bit in FLASH\_CRCCR1/2 and by programming consecutively the target sector numbers in the CRC\_SECT field of the FLASH\_CRCCR1/2 register. Set ADD\_SECT bit after each CRC\_SECT programming.
4. Start the CRC operation by setting the START\_CRC bit.
5. Wait until the CRC\_BUSY flag is reset.
6. Retrieve the CRC result in the FLASH\_CRCDATAR register.

The CRC can be computed for a whole bank by setting the ALL\_BANK bit in the FLASH\_CRCCR1/2 register.

*Note:* Running a CRC on PCROP- or secure-protected user Flash area may alter the expected CRC value.

### 3.3.7 Flash program and erase operations

#### Overview of program/erase operations

The Flash interface implements single error correction and double error detection (see [Section 3.3.5: Error code correction \(ECC\)](#)). The ECC algorithm is built so that a full “zero” data generates a full “zero” ECC code, and a full “ones” data generates full “ones” ECC codes.

Since a 10-bit ECC code is associated to each 256-bit data Flash word, only write operations by 256 bits are supported.

To restore the virgin state, an erase of the entire sector is required.

The Flash memory interface supports multiple program operations:

- Write to user sectors
- Erase user sectors
- Erase bank 1, bank 2 or both banks
- Change user option bytes

The write accesses issued through the AXI interface can be considered as bufferable and not cacheable except that it is not possible to read back the write buffer inside the Flash interface.

The embedded Flash memory can be programmed using in-circuit programming or in-application programming.

#### Write buffer structure and hints

The Flash interface write queue buffer can contain 2 requests. As a result, when several write accesses are requested to the Flash interface, they are accepted until the write queue buffer becomes full. When it is full, the Flash interface stalls the AXI bus.

The operations are executed in the order in which they have been received by the Flash interface. The system is not stalled unless the write command queue and the write buffer are full (2 write operations are already ongoing).

During a normal write operation, the PG1/2 bit must be set to ‘1’ (see [Section : Enabling write operation](#)). Write accesses must then fill in the 256-bit write buffer. When it is full, its content is automatically transferred to the write queue buffer. The effective write operation is executed as soon as the Flash is ready and the previously requested operations have been served.

When the write buffer is partially filled, a write operation can be forced before filling entirely the write buffer. This is done by setting the FW1/2 bits in FLASH\_CR1/2. In this particular case, the unwritten bits are automatically set to “high” value. If no bit in the write buffer is set to “low”, the FW1/2 bit has no effect.

*It is not recommended to overwrite a not virgin Flash word. The result may result in an inconsistent ECC code. The Flash interface can report systematically ECC errors. A valid scenario that can be supported is to overwrite with all zero data. In this case the corresponding ECC code will also be all zero. Consequently, no ECC errors will be detected during the read.*

The write buffer also supports incremental write burst accesses. It allows wrap burst write accesses only when they do not cross 32-byte aligned addresses (Flash word = 256 bits).

## Configuring the programming parameters

The user application must configure the programming parameters prior to performing a program/erase operation:

1. Unlock and program the Flash configuration registers (FLASH\_CR1/2):

The Flash interface implements two Flash control registers: FLASH\_CR1 for bank 1 and FLASH\_CR2 for bank 2. After reset, these registers are write-protected to avoid unwanted operations on the Flash memory (e.g. due to electric disturbances). The following sequence is used to unlock FLASH\_CR1/2 registers:

- a) Write KEY1 = 0x45670123 in the FLASH\_KEYR1/2 register.
- b) Write KEY2 = 0xCDEF89AB in the FLASH\_KEYR1/2 register.

The LOCK1/2 bit in FLASH\_CR1/2 register are automatically cleared. Any wrong sequence locks up FLASH\_CR1/2 until the next system reset. In this case, a bus error is generated.

In addition, the FLASH\_CR1/2 remains locked and a bus error is generated when the following operations are executed:

- programming a third key value,
- writing to a different register belonging to the same bank than FLASH\_KEYR1/2 before FLASH\_CR1/2 has been completely unlocked (KEY1 programmed but KEY2 not yet programmed).
- writing less than one Flash word to KEY1 or KEY2.

To lock again the FLASH\_CR1/2 registers, set the corresponding LOCK1/2 bit to '1' by software.

*Note:* The FLASH\_KEYR1/2 are only accessible at word level.

2. Unlock the Flash option configuration register (FLASH\_OPTCR):

To modify the option bytes, unlock the FLASH\_OPTCR register. Since option bytes are common to both banks, only one FLASH\_OPTCR register exists in the Flash interface and FLASH\_OPTCR is not impacted by bank swapping. The register is aliased and therefore accessible at two different addresses:

- 0x018
- 0x118

After reset, the OPTLOCK bit is set to '1' and FLASH\_OPTCR is locked. The following sequence is required to unlock the FLASH\_OPTCR register:

- a) Write 0x08192A3B to OPTKEY1 in the FLASH\_OPTKEYR register.
- b) Write 0x4C5D6E7F to OPTKEY2 in the FLASH\_OPTKEYR register

After executing this sequence, the OPTLOCK bit is cleared and FLASH\_OPTCR is unlocked. Any wrong key sequence locks up FLASH\_OPTCR until the next system reset and generates a bus error.

In addition, the FLASH\_OPTCR remains locked and a bus error is generated when the following operations are executed:

- programming a third key value,
- writing to a different register before FLASH\_OPTCR has been completely unlocked (OPTKEY1 programmed but OPTKEY2 not yet programmed)
- writing less than one Flash word to OPTKEY1 or OPTKEY2.

To lock again the FLASH\_OPTCR register, set the OPTLOCK bit to '1' by software.

*Note:* The FLASH\_OPTCR is only accessible at word level.

3. Set the programming parallelism:

The parallelism is the maximum number of bits that can be written to '0' in one shot during a write operation. The programming parallelism is also used during sector and bank erase.

There is no hardware limitation on programming parallelism. The user can select different parallelisms depending on the application requirements: the lower the parallelism, the lower the peak consumption during a programming operation, but the longer the execution time.

The parallelism is configured through the PSIZE1/2 bits in FLASH\_CR1/2. Two distinct values can be defined for bank 1 and 2 (refer to [Table 8](#)).

**Table 8. Parallelism parameter**

PSIZE1/2	Parallelism
00	byte (8 bits)
01	half-word (16 bits)
10	word (32 bits)
11	double-word (64 bits)

4. Set the programming delay:

Programming operation timing constraints depend of the Flash interface frequency, which directly impacts the performance. If timing constraints are too tight, the Flash memory will not operate correctly, if they are too lax, programming speed will not be optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH\_ACR register. This configuration register is common to both banks. Refer to [Table 9](#) for the recommended programming delay depending on the Flash interface frequency.

**Table 9. Programming speed**

Recommended WRHIGHFREQ value	Flash interface frequency (MHz)
00	85
01	185

After modifying WRHIGHFREQ, check that the new value has been correctly taken in account by reading it back.

*Note:* When the programming speed is modified while a program/erase operation is ongoing, the new value will be taken into account only after the current operation is complete.

**Enabling write operation**

Prior to programming, the PG1/2 bit must be set in FLASH\_CR1/2. FLASH\_CR1/2 must be previously unlocked. Any write access requested while the PG1/2 bit is set to '0' will be rejected. In this case, no error is generated on the bus, but the PGSEERR1/2 flag is raised.

### Checking write protections

The protection properties of the write transaction target are checked at the output of the write queue buffer, just before the effective write to the Flash memory. No check is performed when the Flash interface accepts AXI write requests. If a write protection violation is detected, the write operation is canceled and a flag corresponding to the protection violation raised in the FLASH\_SR1/2 register. If the write operation is valid, the 10-bit ECC code is concatenated to the 256-bits of data and the write to the Flash memory is effectively executed.

The write protection flag must be cleared before performing a new program/erase operation.

### Write status busy flags

Three different status flags located in FLASH\_SR1/2 are available for each bank. They indicate the ongoing write operation status:

- **BSY1/2**: This bit indicates that an effective write, erase or option byte change operation is ongoing to the Flash memory.
- **QW1/2**: This bit indicates that a program, erase or option byte change operation is pending. This bit remains high until the write operation is complete. It supersedes the BSY1/2 status bit.
- **WBNE1/2**: This bit indicates that the write buffer is not empty. It is reset as soon as the write command is queued.

*Note:* Since the write buffer corresponds to 256-bit Flash words aligned on 32-byte addresses, it is not possible to start writing a new Flash word if another write operation is ongoing.

### Simple write sequence (recommended)

1. Set PG1/2 bit in the FLASH\_CR1/2 register of the targeted bank (bank1/2) (see [Section : Enabling write operation](#)).
2. Check the protection of the target memory area (see [Section : Checking write protections](#)).
3. Write one Flash word corresponding to 32-byte data starting at 32-byte aligned address.
4. Check that BSY1/2 has been raised and wait until it is reset (see [Section : Write status busy flags](#)).

### Optimal block write sequence

This sequence can be used to program a block to Flash memory:

1. Set PG1/2 bit in the FLASH\_CR1/2 register of the corresponding bank (bank1/2) (see [Section : Enabling write operation](#)).
2. Check the protection of the target memory area (see [Section : Checking write protections](#)).
3. Write successively 32 data bytes (Flash words) until the whole block is transferred. Each Flash word must start at an 32-byte aligned address.

### Release the Flash interface to allow the system switching to Stop or Standby mode

If one of the busy flags is active, the microcontroller cannot switch the D1 domain to Stop or Standby mode (see [Section 6: Power control \(PWR\)](#)). There are two ways to release the Flash interface:

- Reset the WBNE1/2 busy flag by any of the following actions:
  - a) Complete the write buffer with missing data.
  - b) Force the write operation without filling the missing data by activating the FW1/2 bit in FLASH\_CR1/2. This will force all missing data “high”.
  - c) Reset the PG1/2 bit in FLASH\_CR1/2. This will disable the write buffer and consequently lead to the loss of its content.
- Poll BSY1/2 and QW1/2 busy bits until they are cleared. This will indicate that all recorded write, erase and option change operations are complete.

The microcontroller can then switch to Stop or Standby mode.

### Flash sector erase

To erase a 128-Kbytes user sector proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation (refer to [Section 3.3.9: Flash interface error flags](#) for details).
2. Unlock the FLASH\_CR1/2 register, as described in [Section : Configuring the programming parameters](#).
3. Set the SER1/2 bit and SNB1/2 bitfield in the corresponding FLASH\_CR1/2 register. SER1/2 indicates a sector erase operation, while SNB1/2 contains the target sector number.
4. Set the START1/2 bit in the FLASH\_CR1/2 register.
5. Wait for the BSY1/2 bit to be cleared in the corresponding FLASH\_SR1/2 register.

*Note:* If a bank erase is requested simultaneously to the sector erase (BER1/2 bit set), the bank erase operation supersedes the sector erase operation.

### Standard Flash bank erase

To erase all bank sectors excepted for those containing secure and protected data, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation (refer to [Section 3.3.9: Flash interface error flags](#) for details).
2. Unlock the FLASH\_CR1/2 register, as described in [Section : Configuring the programming parameters](#).
3. If a PCROP-protected area exists, DMEP1/2 bits both in FLASH\_PRAR\_CUR1/2 and FLASH\_PRAR\_PRG1/2 registers shall be set to 0.
4. If a secure-only area exists, DMES1/2 bits both in FLASH\_SCAR\_CUR1/2 and FLASH\_SCAR\_PRG1/2 registers shall be set to 0.
5. Set the BER1/2 bit in the FLASH\_CR1/2 register corresponding to the target bank.
6. Set the START1/2 bit in the FLASH\_CR1/2 register to start the bank erase operation. Then wait until the BSY1/2 bit is cleared in the corresponding FLASH\_SR1/2 register.

*Note:* *BER1/2 and START1/2 bits can be set together and steps 8 and 9 merged.*  
*If a sector erase is requested simultaneously to the bank erase (SER1/2 bit set), the bank erase operation supersedes the sector erase operation.*

### Flash bank erase with automatic protection removal

To erase all bank sectors including those containing secure and protected data, without performing an RDP regression, proceed as follows:

1. Check that no Flash memory operation is ongoing by monitoring the BSY1/2 bits in FLASH\_SR1/2 register.
2. Check and clear (optional) all the error flags due to previous programming/erase operation (refer to [Section 3.3.9: Flash interface error flags](#) for details).
3. Unlock FLASH\_OPTCR register, as described in [Section : Configuring the programming parameters](#).
4. If a PCROP-protected area exists, set DMEP1/2 bit either in FLASH\_PRAR\_CUR1/2 or FLASH\_PRAR\_PRG1/2 register. In addition, program the PCROP area end and start addresses so that the difference is negative, that is:  

$$\text{PROT\_AREA\_END1/2} < \text{PROT\_AREA\_START1/2}$$
5. If a secure-only area exists, set DMES1/2 bit either in FLASH\_SCAR\_CUR1/2 or FLASH\_SCAR\_PRG1/2 register. In addition, program the secure area end and start addresses so that the difference is negative, that is:  

$$\text{SEC\_AREA\_END1/2} < \text{SEC\_AREA\_START1/2}$$

*Note:* *Step 5 can only be performed by ST secure library or by an application running in Secure mode. However it is only mandatory when a secure-only area exists.*

6. Set all WRPSn1/2 bits in FLASH\_WPSN\_PRG1/2R to 1 to disable all sector write protection.
7. Unlock FLASH\_CR1/2 register.
8. Set the BER1/2 bit in the FLASH\_CR1/2 register corresponding to the target bank.
9. Set the START1/2 bit in the FLASH\_CR1/2 register to start the bank erase with protection removal operation. Then wait until the BSY1/2 bit is cleared in the corresponding FLASH\_SR1/2 register. At that point a bank erase operation erases the whole bank including the sectors containing PCROP-protected and/or secured data, and an option byte change is automatically performed so that all the protections are disabled.

*Note:* *BER1/2 and START1/2 bits can be set together and steps 8 and 9 merged.*

---

**Warning:** Please note the following warnings, with regard to above sequence:

- It is not possible to execute the above sequence on one bank while also modifying the protection parameters of the other bank.
- No other option bytes than those indicated above must be changed, and no protection change must be performed in the bank that is not targeted by the bank erase with protection removal request.
- When one or both of the events above occur(s), a simple

---

**bank erase takes place, no option byte change occurs and no option change error is set.**

---

### Flash mass erase

To erase all sectors of both banks simultaneously, excepted for those containing secure and protected data, the user application can set the MER bit to 1 in FLASH\_OPTCR register, as described below:

1. Check that no Flash memory operation is ongoing by monitoring the BSY1/2 bits in FLASH\_SR1/2.
2. Check and clear (optional) all the error flags due to previous programming/erase operation (refer to [Section 3.3.9: Flash interface error flags](#) for details).
3. Unlock the two FLASH\_CR1/2 registers plus FLASH\_OPTCR register, as described in [Section : Configuring the programming parameters](#).
4. If a PCROP-protected area exists, DMEMP1/2 bits both in FLASH\_PRAR\_CUR1/2 and FLASH\_PRAR\_PRG1/2 registers shall be set to 0.
5. If a secure-only area exists, DMES1/2 bits both in FLASH\_SCAR\_CUR1/2 and FLASH\_SCAR\_PRG1/2 registers shall be set to 0.
6. Set the MER bit to 1 in FLASH\_OPTCR register. It automatically sets BER1, BER2, START1 and START2 to 1, thus launching a bank erase operation on both banks. Then wait until the BSY1/2 bit is cleared in the corresponding FLASH\_SR1/2 register.

### Flash mass erase with automatic protection removal

To erase all sectors of both banks simultaneously, including those containing secure and protected data, and without performing an RDP regression, proceed as follows:

1. Check that no Flash memory operation is ongoing by monitoring the BSY1/2 bits in FLASH\_SR1/2.
2. Check and clear (optional) all the error flags due to previous programming/erase operation.
3. Unlock the two FLASH\_CR1/2 registers plus FLASH\_OPTCR register.
4. If a PCROP-protected area exists, set DMEMP1/2 bit either in FLASH\_PRAR\_CUR1/2 or FLASH\_PRAR\_PRG1/2 register. In addition program the PCROP area end and start addresses so that the difference is negative.
5. If a secure-only area exists set DMES1/2 bit either in FLASH\_SCAR\_CUR1/2 or FLASH\_SCAR\_PRG1/2 register. In addition program the secure area end and start addresses so that the difference is negative.

*Note:* Step 5 can only be performed by ST secure library or by an application running in Secure mode. it is however only mandatory when a secure-only area exists.

6. Set all WRPSn1/2 bits in FLASH\_WPSN\_PRG1/2R to 1 to disable all sector write protection.
7. Set the MER bit to 1 in FLASH\_OPTCR register, then wait until the BSY1/2 bit is cleared in the corresponding FLASH\_SR1/2 register. At that point a Flash bank erase with automatic protection removal is executed on both banks.

### 3.3.8 Changing user option bytes

The user option byte change operation can be used to modify the configuration and the protection settings saved as the Flash memory option byte area (see [Table 10: List of Flash user option bytes](#) for a detailed list).

The Flash interface features two sets of option byte registers:

- The first register set contains the current values of the option bytes. Their names has the `_CUR` extension. All “`_CUR`” registers are read-only. Their values are automatically loaded after power-on or after an option byte change operation.
- The second register set allows modifying the option bytes. Their names contains the `_PRG` extension. All “`_PRG`” registers can be accessed in read/write mode.

When the `OPTLOCK` bit in `FLASH_OPTCR` register is set, modifying the `FLASH_OPTXX_PRG` registers is forbidden.

When `OPTSTART` bit is set to ‘1’, the Flash interface checks if at least one option byte needs to be programmed by comparing the current values (`_CUR`) with the new ones (`_PRG`).

An option byte change operation is granted only if the following condition are met:

- Current RDP is not level 2 (except for `SWAP` bit which can be changed whatever the level).
- If a `PCROP`-protected area exists, then the new programmed area must be greater or equal to the current one (except during a regression level).
- If a secure-protected area exists, then this area can be modified when the secure mode is set (see [Section 4: Security memory management](#)).
- In case of level regression (change from level 1 to level 0), `DMEP1/2` option bit can be set without limitations, otherwise it can only be set to ‘1’.
- `DMES1/2` option bit can be modified in `FLASH_SCAR_PRG1/2` only by simultaneously performing a level regression (change from level 1 to level 0), otherwise it can only be set to ‘1’.
- When the `SECURITY` option bit is set and a `PCROP` or secure area exists, the protection can be reset (`SECURITY` bit reset) by performing a level regression and programming the `PCROP` or secure area end and start addresses so that the difference is negative.

If one of these conditions is not respected, the Flash interface sets the `OPTCHANGEERR` flag to ‘1’ in the `FLASH_OPTSR_CUR` register and aborts the option byte change operation.

#### Option byte modification sequence

To modify user option bytes, follow the procedure below:

1. Unlock `OPTLOCK` bit according to the specific sequence described in [Section : Configuring the programming parameters](#).
2. Write the desired option byte value in the corresponding option registers: `FLASH_XXX_PRG1/2`.
3. Set the Options Start `OPTSTART` bit in the `FLASH_OPTCR` register.
4. Wait until `OPT_BUSY` bit is cleared.

**Note:** *If a reset or a power-down occurs while the option byte modification is ongoing, the old option byte values are kept. A new option byte modification sequence is required to program the new values.*

### 3.3.9 Flash interface error flags

The Flash interface reports when an error occurred during a program/erase operation. The user application can individually enable the interrupt for each error. Some errors need to be cleared before a new write starts.

Each bank has a dedicated set of error flags in order to identify which bank generated the error: they are available in Flash Status register 1 or 2 (FLASH\_SR1/2).

Each error flag is associated to an interrupt enable bit in FLASH\_CR1/2. When the interrupt enable bit is set to '1', an interrupt is generated when the corresponding error flag is raised to '1'. To clear an error flag, set the corresponding bit in the FLASH\_CCR1/2 register.

#### Write protection error (WRPERR1/2)

The WRPERR1/2 flag is a sticky bit which is set by hardware when the user application attempts to program/erase a protected area. When this flag is raised, the operation is aborted and nothing is changed. This flag is cleared by setting CLR\_WRPERR1/2 bit in FLASH\_CCR1/2 register to '1'. If WRPERRIE1/2 bit in FLASH\_CR1/2 register is set to '1', an interrupt is generated when WRPERR1/2 flag is raised.

WRPERR1/2 must be cleared before starting a new write operation, otherwise a sequence error (PGSERR1/2 bit) is generated and the next program operation is aborted.

#### Programming sequence error (PGSERR1/2)

The PGSERR1/2 flag is a sticky bit which is set by hardware when the programming sequence is incorrect. This bit is set to '1' when one of the following condition is met:

- A write operation is requested by the AXI bus but PG1/2 bit has not yet been set.
- The write protection error flag (WRPERR1/2) has not been reset and a new write operation is requested.
- The inconsistency error (INCERR1/2) has not been reset and a new write operation is requested.
- The Flash operation error (OPERR1/2) has not been reset and a new write operation is requested.

When PGSERR1/2 flag is raised, the program operation is aborted. To clear this flag, set CLR\_PGSERR1/2 bit in FLASH\_CCR1/2 register to '1'. If PGSERRIE1/2 bit is set in FLASH\_CR1/2, an interrupt is generated when PGSERR1/2 flag is raised.

PGSERR1/2 must be cleared before starting a new write operation.

#### Strobe error (STRBERR1/2)

The STRBERR1/2 flag is a sticky bit which is set by hardware when the user application writes several times the same byte in the write buffer. The write operation is not aborted and the application can ignore the error, proceed with the current write operation and request new write operations. This flag is cleared by setting the CLR\_STRBERR1/2 bit in FLASH\_CCR1/2. If STRBERRIE1/2 bit is set in FLASH\_CR1/2, an interrupt is generated when STRBERR1/2 flag is raised.

It is not mandatory to clear STRBERR1/2 flag before starting a new write operation.

### Inconsistency error (INCERR1/2)

The INCERR1/2 flag is a sticky bit which is set by hardware in the following cases:

- when the user application starts a write operation to a Flash word (with a first burst) and sends a new burst write to a different Flash word address before the ongoing write operation is complete. In this case, the write buffer is emptied, the new data are rejected and INCERR1/2 flag is raised.
- when a master starts a write operation to a Flash word (with a first burst) and another master sends a new write burst to the same or a new Flash word address before the operation initiated by the first master is complete. In this case, the write buffer is emptied, the new data is rejected and INCERR1/2 flag is raised.
- when a wrap burst issued by a master overlaps two or more Flash-word address (the maximum size of a wrap burst being limited to the Flash-word size, that is 256 bits).

When the INCERR1/2 flag is raised, the operation is aborted and no write operation is executed. To clear this flag, set the CLR\_INCERR1/2 bit in FLASH\_CCR1/2 register. If INCERRIE1/2 bit in FLASH\_CR register is set, an interrupt is generated when INCERR1/2 flag is raised.

INCERR1/2 flag must be cleared before starting a new program or erase operation, otherwise a sequence error (PGSERR1/2 bit) is generated and the next program operation is aborted.

### Operation error (OPERR1/2)

The OPERR1/2 flag is a sticky bit which is set by hardware when the Flash memory detects an error during a write or erase operation. This error may be caused by an incorrect Flash memory behavior due to cycling issues.

To clear this flag, set to '1' the CLR\_OPERR1/2 bit in FLASH\_CCR1/2 register. If OPERRIE1/2 bit in FLASH\_CR1/2 register is '1', an interrupt is generated when OPERR1/2 flag is raised.

OPERR1/2 must be cleared before starting a new program operation, otherwise a sequence error (PGSERR1/2 bit) is generated and the new programming is aborted.

### 3.3.10 Simultaneous read/program/erase on bank1 and bank2

The Flash memory is divided into two independent banks. The Flash interface can drive different operations at the same time on each bank. A read, program or erase operation can be executed on bank 1 while another read, program or erase operation is executed on bank 2.

An exception exists for option byte change when a level regression is required: in this case, the availability of both banks is needed.

### 3.3.11 FLASH option bytes

#### Option byte description

The option bytes are configured by the end user depending on the application requirements. The user option bytes are accessible through the Flash interface registers interface. The programming sequence of option byte is described in [Section : Option byte modification sequence](#).

To increase the robustness of option byte storage in the Flash interface, each option byte data is associated to an error code correction (ECC) inside the Flash memory.

[Table 10](#) describes the list of all user option bytes available in the Flash interface registers.

**Table 10. List of Flash user option bytes**

User option	Register <sup>(1)</sup>	Size (bits)	Default factory programmed value <sup>(2)</sup>
SWAP_BANK	FLASH_OPTSR_CUR	1	0x0
RDP	FLASH_OPTSR_CUR	8	0xAA
BOR_LEV	FLASH_OPTSR_CUR	2	0x1
BOOT_ADD0	FLASH_BOOT_CURR	16	0x0800
BOOT_ADD1	FLASH_BOOT_CURR	16	0x1FF0
DMEP1	FLASH_PRAR_CUR1	1	0x0
DMES1	FLASH_SCAR_CUR1	1	0x0
WRPSn1	FLASH_WRP_CUR1R	8	0xFF
PROT_AREA_START1	FLASH_PRAR_CUR1	12	0xFF
PROT_AREA_END1	FLASH_PRAR_CUR1	12	0x00
SEC_AREA_START1	FLASH_SCAR_CUR1	12	0xFF
SEC_AREA_END1	FLASH_SCAR_CUR1	12	0x00
DMEP2	FLASH_PRAR_CUR2	1	0x0
DMES2	FLASH_SCAR_CUR2	1	0x0
WRPSn2	FLASH_WPSN_CUR1R	8	0xFF
PROT_AREA_START2	FLASH_PRAR_CUR2	12	0xFF
PROT_AREA_END2	FLASH_PRAR_CUR2	12	0x00
SEC_AREA_START2	FLASH_SCAR_CUR2	12	0xFF
SEC_AREA_END2	FLASH_SCAR_CUR2	12	0x00
IWDG1_HW	FLASH_OPTSR_CUR	1	0x1
SECURITY	FLASH_OPTSR_CUR	1	0x0
ST_RAM_SIZE	FLASH_OPTSR_CUR	2	0x10
nRST_STBY_D1	FLASH_OPTSR_CUR	1	0x1
nRST_STOP_D1	FLASH_OPTSR_CUR	1	0x1
FZ_IWDG_SDBY	FLASH_OPTSR_CUR	1	0x1

Table 10. List of Flash user option bytes (continued)

User option	Register <sup>(1)</sup>	Size (bits)	Default factory programmed value <sup>(2)</sup>
FZ_IWDG_STOP	FLASH_OPTSR_CUR	1	0x1
PERSO_OK	FLASH_OPTSR_CUR	1	0x1
IO_HSLV	FLASH_OPTSR_CUR	1	0x0

1. Bit mapping and detailed bit description are available in [Section 3.5: FLASH registers](#).
2. The default factory option bytes values are the default values before first option byte change.

### Option byte loading

There are three ways to load Flash user option bytes:

1. At Power-on:  
The Flash interface automatically loads user option bytes from the Flash memory. During the loading sequence, the device remains under reset and the Flash interface is not accessible.
2. When D1 power domain, which contains the Flash interface, is switched from Standby mode to Run mode:  
In this case the Flash interface behaves as during a power-on sequence except that the device does not remain under reset.
3. When the user application modifies the option byte content through the Flash interface registers:  
In this case, after the Flash interface has reprogrammed the option byte sectors, an option byte reloading is done to update the Flash interface option registers.

### Rules for changing specific option bits

Some of the option byte field must respect specific rules before being updated with new values. These fields, as well as the associated constraints, are described below:

- Secure area size  
The secure area size is controlled by SEC\_AREA\_START1/2, SEC\_AREA\_END1/2 and DMES1/2 located in the FLASH\_SCAR\_CUR1/2 and FLASH\_SCAR\_PRG1/2 registers. These option bytes can be modified in secure mode. When the SEC\_AREA\_END1/2 field is lower than SEC\_AREA\_START1/2, the secure area size is null. If SEC\_AREA\_START1/2 = SEC\_AREA\_END1/2, all banks are secure protected. For more details refer to [Section 4: Security memory management](#).
- DMES1/2  
When this option bit is set, the secure area is erased during a level regression (level 1 to level 0) or a bank erase with all protections removed, otherwise it is preserved. Resetting this bit can be done only when a level regression or a bank erase with all protections removed is requested at the same time. For more details refer to [Section 4: Security memory management](#).
- PCROP area size (execute-only)  
The PCROP area size is controlled by PROT\_AREA\_START1/2, PROT\_AREA\_END1/2 and DMEP1/2 in the FLASH\_PRAR\_CUR1/2 and FLASH\_PRAR\_PRG1/2 registers. Increasing the PCROP area can be done without any restriction. To reduce or remove the PCROP area, a level regression must be

requested at the same time. PCROP areas can be deleted by performing a bank erase with all protections removed. When the PROT\_AREA\_END1/2 field is lower than the PROT\_AREA\_START1/2 one, the PCROP area size is null. If PROT\_AREA\_START1/2 = PROT\_AREA\_END1/2, all banks are PCROP protected. For more details refer to [Section 4: Security memory management](#).

- DMEP1/2  
When this bit is set, the PCROP area is erased during a level regression or a bank erase with all protections removed. When it is not set, the PCROP area is preserved during a level regression (level 1 to level 0). There are no restriction in setting this bit. However, resetting this bit can only be done when a level regression or a bank erase is requested at the same time.
- Readout protection (RDP)
  - When RDP is set to level 2, there is no way to return to a lower level. If the user application attempts to perform such an operation, an error is raised and the required change is ignored.
  - When the RDP is set to level 1, RDP option byte modification is allowed without any restriction if the user application requests to switch to RDP level 2.
  - However switching from level1 to level 0 leads to a Flash mass erase if DMES1/2 in FLASH\_SCAR\_CUR1/2 and DMEP1/2 bit in FLASH\_PRAR\_CUR1/2 are set to '1' for the corresponding bank.
  - If the user application wants to keep the PCROP area or the secure area during a level regression, DMEP1/2 or DMES1/2 bit must have been set to '0' prior to performing the level regression.
  - When RDP is set to level 0, switching to level 1 or level 2 is possible without any restriction.
- Sector Write Protection (WRPSn1/2)  
No specific rules.
- Security mode (SECURITY)  
Setting this option bit activates the device security mode. This bit can be cleared when no Secure or PCROP areas exist, otherwise a level regression or a Security boot service must be executed to reset this bit. For more details please refer to [Section 4: Security memory management](#).
- ST\_RAM\_SIZE  
The value of this option byte can be increased without any restriction. Decreasing this value is only authorized through root secure services. This option is effective only when the SECURITY option byte is set. For more details please refer to [Section 4: Security memory management](#).

### 3.3.12 Protection mechanisms

The Flash interface implements different protection mechanisms:

- Readout protection (RDP)
- PCROP (Proprietary code readout protection): execute-only area
- Secure protection
- Sector write protection.

## RDP (Readout protection)

A Flash user area can be protected against read operations by an untrusted code. Three read protection levels exist (refer to [Table 11: RDP value vs readout protection level](#), [Table 12: Allowed accesses versus Readout protection level](#) and [Figure 6: Protection transition scheme](#)):

- Level 0: no read protection

When the read protection level is set to level 0 by writing 0xAA into the read protection option byte (RDP), all read/program operations (if no others protections are set) from/to the Flash memory or the backup SRAM are possible whatever the boot configuration (Flash user boot, debug or boot from RAM).
- Level 1

The read protection level 1 is activated by writing any value (except for 0xAA and 0xCC used to set level 0 and level 2, respectively) into the RDP option byte. When the read protection level 1 is set:

  - No access (read, erase, program) to Flash memory or backup SRAM can be performed when the debugger is connected or when the boot configuration is different from user Flash. A bus error is generated when a read access to the Flash memory is requested.
  - When booting from Flash memory (no debugger connected), read, erase and program accesses from/to Flash memory and backup SRAM from user code are allowed.
  - When level 1 is active, programming the protection option byte to level 0 (RDP level regression) causes the Flash memory and the backup SRAM to be mass-erased. As a result the user Flash memory area and backup SRAM are cleared before the RDP level is set to level 0. The mass erase will delete the content of both banks and backup SRAM as well as preserve the Flash PCROP and Secure areas if the DMEP1/2 and DMES1/2 bits are to '0'.
- Level 2: debug disabled and RDP enabled

The read protection level 2 is activated by writing 0xCC to the RDP option byte. When the read protection level 2 is set:

  - All protections provided by level 1 are active.
  - Booting from RAM is no more allowed.
  - When security is enabled, the boot is forced in the secure System Flash memory (see [Section 4: Security memory management](#)).
  - Booting from System Flash memory is no more allowed, excepted when the security is enabled. The boot is forced in the secure System Flash (see [Section 4: Security memory management](#)).
  - All Debug features are disabled.
  - User option bytes can no longer be changed except for the SWAP bit (see [Section 3.3.13: Flash bank swapping](#)).
  - When booting from Flash memory, read, erase and program accesses to Flash memory and backup SRAM from user code are allowed. Memory read protection level 2 is an irreversible operation. When level 2 is activated, the level of protection cannot be decreased to level 0 nor level 1.

**Note:** *The JTAG port is permanently disabled when level 2 is active (acting as a JTAG fuse). As a consequence, STMicroelectronics is not able to perform analysis on the defective parts on which the level 2 protection has been set.*

Table 11. RDP value vs readout protection level

RDP option byte value	Readout protection level
0xAA	level 0
0xCC	level 2
Any other value	level 1

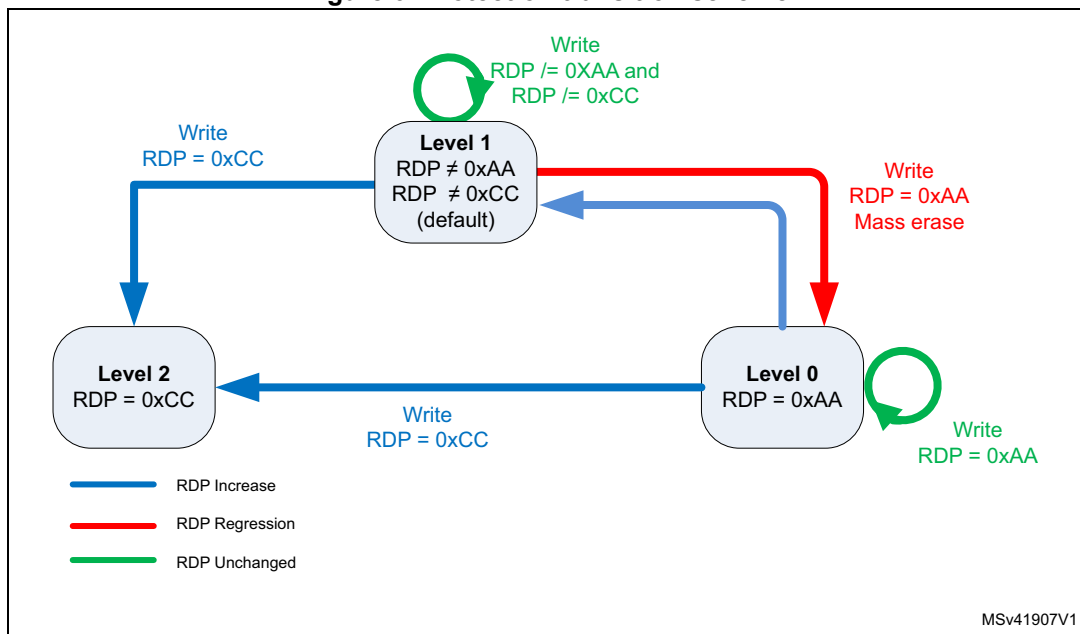

Table 12. Allowed accesses versus Readout protection level

Area	Protection level (RDP)	Boot = user Flash memory <sup>(1)</sup>	Boot != user Flash memory or Debug memory connected
User Flash memory	1	R/W/E	No Access
	2	R/W/E	_(2)
System Flash memory	1	R	R
	2	R	_(2)
Option bytes	1	R/W/E	R/W/E
	2	R	_(2)
Backup SRAM	1	R/W	No Access
	2	R/W	_(2)

1. W: Write, R: Read, E: Erase.

2. When RDP = Level 2, no Debug feature is available, no other Boot than User Flash is possible, modification of option bytes is not allowed excepted for the SWAP bit field.

Figure 6. Protection transition scheme

### PCROP area (proprietary code readout protection, execute-only area)

The Flash interface allows defining an “executable-only” area in each Flash bank. This area permits only instruction fetch transactions. No data access (data or literal pool) is allowed. The native code must be compiled accordingly with “execute-only” option. The execute-only area helps protecting software intellectual property.

Two different PCROP regions can be defined (one per Flash bank) by setting the PROT\_AREA\_END1/2 and PROT\_AREA\_START1/2 option bytes so that the resulting difference is positive and not null (END address higher than START address).

The minimum PCROP area that can be set is 16 Flash words, that is 512 bytes. The maximum execute-only area that can be set is the whole Flash bank area. This is done by setting PROT\_AREA\_END1/2 and PROT\_AREA\_START1/2 fields to the same value.

The PCROP area can be defined with a granularity of eight Flash words. In others words, the difference between END and START addresses incremented by one and multiplied by eight represents the number of Flash words that are PCROP configured, assuming PROT\_AREA\_END1/2 is strictly higher than PROT\_AREA\_START1/2.

To disable any of the two PCROP areas, the PROT\_AREA\_END1/2 address field must be set to a lower value than PROT\_AREA\_START1/2, meaning that the resulting difference is negative (END address lower than START address).

For example, to set a PCROP area from address 0x08000000 (included) to address 0x08000FFF (included), corresponding to 4 Kbytes starting from the bank 1 base address of the first bank, PROT\_AREA\_START1 and PROT\_AREA\_END1 registers must be respectively programmed to:

- PROT\_AREA\_START1 = 0x000
- PROT\_AREA\_END1 = 0x00F

The protected area size is equal to:

$$[(\text{PROT\_AREA\_END} - \text{PROT\_AREA\_START}) + 1] \times 256 = 16 \times 256 \text{ bytes} = 4 \text{ Kbytes.}$$

#### PCROP area properties

- Read (not fetch) transaction performed from a PCROP area will raise the RDPERR flag in the FLASH\_SR1/2 register.
- Write transaction performed to a PCROP area will raise the WRPERR flag in the FLASH\_SR1/2 register.
- When a PCROP area is already defined, the area size can still be increased either by reducing the START address, or by increasing the END address field. Two sequences can be used to disable the PCROP area:

- Perform an RDP level regression (level 1 to level 0), enable the DMEP1/2 bit and set the PROT\_AREA\_START1/2 to a value higher than PROT\_AREA\_END1/2 in the FLASH\_PRAR\_PRG1/2 registers.

PCROP protection is independent from the RDP protection. However, in this case, prior to removing PCROP, RDP should be first set to level 1 to enable a RDP level regression.

- Request a bank erase operation while enabling at the same time DMEP1/2, DMES1/2 and all WRPSn1/2 bits to ‘1’, set the PROT\_AREA\_START1/2 higher than PROT\_AREA\_END1/2 in the FLASH\_PRAR\_PRG1/2 and SEC\_AREA\_START1/2 higher than SEC\_AREA\_END1/2 in FLASH\_SCAR\_PRG1/2.

## Secure area

The Flash interface allows setting a “secure” area in each Flash bank. The data and program stored in this area cannot be accessed unless the secure mode is set. The secure area helps isolating secure user code from application non-secure code. For example, the secure area can be used to protect a secure firmware upgrade code, a secure boot code.

Two different secure regions can be defined (one per Flash bank) by setting the SEC\_AREA\_END1/2 and SEC\_AREA\_START1/2 option bytes so that the resulting difference is positive and not null (END address higher than START address). Please note that these option bytes can be modified only in secure mode (see [Section 4: Security memory management](#)).

The size of the smaller secure area that can be set is 512 bytes. The maximum secure area size is the whole Flash bank. This can be done by setting SEC\_AREA\_END1/2 and SEC\_AREA\_START1/2 fields to the same value.

The secure area can be defined with a granularity of eight Flash words. In others words, the difference between the END and START addresses incremented by one and multiplied by eight represents the number of Flash words that are secure protected, assuming SEC\_AREA\_END1/2 is strictly higher than SEC\_AREA\_START1/2.

To disable any of the two secure areas, the SEC\_AREA\_END1/2 address field must be set to a value lower than SEC\_AREA\_START1/2, meaning that the resulting difference is negative (END address lower than START address).

For example, to set a Secure area from the address 0x08100000 (included) to address 0x08101FFF (included), corresponding to 8 Kbytes starting from the second bank base address, SEC\_AREA\_START2 and SEC\_AREA\_END2 registers must be respectively programmed to:

- SEC\_AREA\_START2 = 0x000
- SEC\_AREA\_END2 = 0x01F

The secure area size is equal to:

$$[(\text{SEC\_AREA\_END2} - \text{SEC\_AREA\_START2}) + 1] \times 256 = 32 \times 256 \text{ bytes} = 8 \text{ Kbytes.}$$

### Secure area properties

- The secure area size can be modified when security is enabled and under specific conditions (see [Section 4: Security memory management](#)). Two solutions are possible to delete a secure area:
  - Perform an RDP level regression (level 1 to level 0), enable the DMES1/2 bit and set the SEC\_AREA\_START1/2 address to a value higher than SEC\_AREA\_END1/2 in the FLASH\_SCAR\_PRG1/2 registers.  
RDP protection is independent from the secure protection. However, in this case, prior to removing RDP, RDP should be first set to level 1 to enable a RDP level regression.
  - Request a bank erase operation, set at the same time DMEP1/2, DMES1/2 and all WRPSn1/2 bits to '1'. and configure the SEC\_AREA\_START1/2 address to a value higher than SEC\_AREA\_END1/2 in the FLASH\_SCAR\_PRG1/2 and PROT\_AREA\_START1/2 higher than PROT\_AREA\_END1/2 in FLASH\_PRAR\_PRG1/2.

For more details on how to use the security aspects of the device and how to enable/disable user secure mode, refer to [Section 4: Security memory management](#).

### Sector write protection

The purpose of the sector write protection is to protect Flash memory against unwanted modifications of the non-volatile code and/or data. Any Flash sector can be independently write-protected or unprotected by clearing/setting the corresponding WRPSn1/2 bit in the FLASH\_WPSN\_PRG1/2R register.

A write-protected sector can neither be erased nor programmed. As a result, a bank erase cannot be performed if one bank sector is write-protected, unless the bank erase is done in the scope of a level regression. In this case, the bank erase is transformed into a sequence of sector erase operations since only unprotected sectors are erased.

Sector write protection bits (user options) can be modified without restrictions when RDP level is set to level 0 or level 1. When level 2 is set, it is no more possible to change the write protection bitfield in the option bytes.

*Note: By default, a PCROP area is also write-protected. As a result, a sector that partly or entirely belongs to a PCROP area cannot be erased nor programmable.*

### 3.3.13 Flash bank swapping

The Flash interface allows swapping bank 1 and bank 2 memory mapping. This feature can be used after a firmware upgrade to restart the device on the new firmware after a system reset. Bank swapping is controlled by the SWAP\_BANK bit located in the FLASH\_OPTCR register. [Table 13](#) gives the accessible memory map from both AXI slave Flash interfaces depending on SWAP\_BANK option bit configuration.

**Table 13. AXI interfaces memory mapping SWAP\_BANK = '0'**

Area	AXI 1	AXI 2
User Sector Bank 1	Yes <sup>(1)</sup>	No
User Sector Bank 2	No	Yes <sup>(1)</sup>
System Flash Bank 1	Yes <sup>(2)</sup>	No
System Flash Bank 2	No	Yes <sup>(2)</sup>

1. User Bank 1 and 2 are mapped from 0x0800 0000 to 0x080F FFFF and from 0x0810 0000 to 0x081F FFFF, respectively.
2. System Flash Bank 1 and 2 are mapped from 0x1FF0 0000 to 0x1FF1 FFFF and from 0x1FF4 0000 to 0x1FF5 FFFF, respectively.

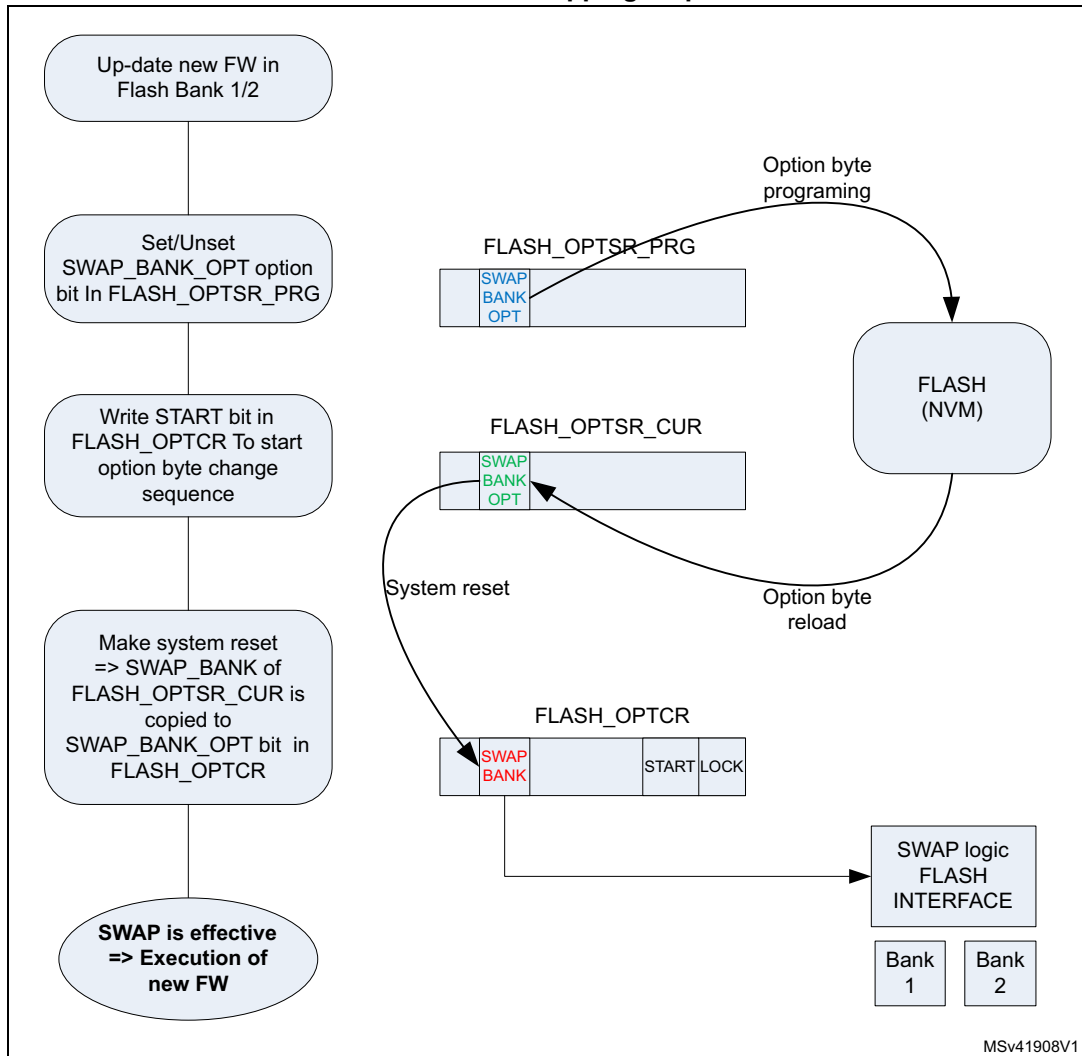

**Table 14. AXI interfaces memory mapping SWAP\_BANK = '1'**

Area	AXI 1	AXI 2
User Sector Bank 1	No	Yes <sup>(1)</sup>
User Sector Bank 2	Yes <sup>(1)</sup>	No
System Flash Bank 1	Yes <sup>(2)</sup>	No
System Flash Bank 2	No	Yes <sup>(2)</sup>

1. User Bank 1 and 2 are mapped from 0x0810 0000 to 0x081F FFFF and from 0x0800 0000 to 0x080F FFFF, respectively.
2. System Flash Bank 1 and 2 are mapped from 0x1FF0 0000 to 0x1FF1 FFFF and from 0x1FF4 0000 to 0x1FF5 FFFF, respectively.

When modifying the SWAP\_BANK\_OPT bit in the FLASH\_OPTSR\_PRG register, the new value is taken into account only when the option bytes have been reloaded from the option byte sector into the FLASH\_OPTSR\_CUR register and its value copied to the SWAP\_BANK bit of the FLASH\_OPTCR register after system reset.

**Table 15. Bank swapping sequence**

Below the recommended sequence to swap bank 1 and bank 2 memory mapping after a firmware update:

1. Update bank 2 or bank 1 with the new firmware.
2. Modify SWAP\_BANK\_OPT bit accordingly in the FLASH\_OPTSR\_PRG register.
3. Start the Option byte change sequence by setting the OPTSTART bit in the FLASH\_OPTCR register. Make sure that the register has been unlocked prior to programming it.
4. Perform a system reset. After the option byte loading sequence, the bank swap is effective and the new firmware shall be executed.

*Note:* The SWAP\_BANK\_OPT option bit in FLASH\_OPTSR\_PRG can be modified whatever the RDP level, even in level 2, thus allowing advanced firmware upgrade in any level of readout protection.

### 3.4 FLASH interrupts

As explained in [Section 3.3.9: Flash interface error flags](#), each flag error can generate an interrupt if the corresponding interrupt enable bit has been set in the FLASH\_CR1/2 register.

The End of Operation (EOP1/2) bit in the FLASH\_SR1/2 register is set when an erase, program or option change operation has successfully completed. Setting the End of Operation Interrupt Enable bit (EOPIE1/2) in the FLASH\_CR1/2 register enables the generation of an interrupt when the erase, program or option change operation has completed.

The EOP1/2 flag can be cleared by writing the corresponding bit in the FLASH\_FCCR1/2 register.

### 3.5 FLASH registers

#### 3.5.1 FLASH access control register (FLASH\_ACR)

Address offset: 0x000 or 0x100

Reset value: 0x0000 0037

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRHIGH FREQ		Res.	LATENCY		
										rw	rw		rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value

Bits 5:4 **WRHIGHFREQ**: Flash signal delay

These bits are used to control the delay between Flash signals during programming operations. The user has to write the correct value depending on the Flash interface frequency (see [Table 7](#)). No check is performed to verify that the configuration is correct.

- 00: ≤ 85 MHz
- 01: ≤ 185 MHz
- 10: ≤ 285 MHz
- 11: ≤ 385 MHz

Bit 3 Reserved, must be kept at reset value

Bits 2:0 **LATENCY**: Read latency

The value of these bits specifies the number of wait states that will be used during read operations on both Flash memory banks. The user has to write the correct value depending on the Flash memory interface frequency and power operating mode as explained in [Table 7](#). No check is performed to verify that the configuration is correct.

- 000: zero wait states used to read a word from Flash memory
- 001: one wait state used to read a word from Flash memory
- ...
- 111: 7 wait states used to read from Flash memory

### 3.5.2 FLASH key register for bank 1 (FLASH\_KEYR1)

Address offset: 0x004

Reset value: 0x0000 0000

Bits 31:0 **KEYR1**: Bank 1 access configuration unlock key

FLASH\_KEYR1 is a write-only register. The following values must be programmed consecutively to unlock FLASH\_CR1 register and allow programming/erasing it:

- a) 1st key = 0x4567 0123
- b) 2ndkey = 0xCDEF 89AB

For more details, refer to [Section : Configuring the programming parameters](#).

### 3.5.3 FLASH option key register (FLASH\_OPTKEYR)

Address offset: 0x008 or 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPTKEYR															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OPTKEYR															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OPTKEYR**: Unlock key option bytes

FLASH\_OPTKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH\_OPTCR register and allow programming/erasing it as well as all \_PRG registers:

- a) 1st key = 0x0819 2A3B
- b) 2nd key= 0x4C5D 6E7F

For more details, see [Section : Configuring the programming parameters](#).

### 3.5.4 FLASH control register for bank 1 (FLASH\_CR1)

Address offset: 0x00C

Reset value: 0x0000 0031

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CRCENDIE1	DBECCERRIE1	SNECCERRIE1	RDSERRIE1	RDPERRIE1	OPERRIE1	INCERRIE1	Res.	STRBERRIE1	PGSERRIE1	WRPERRIE1	EOPIE1
				r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_EN	Res.	Res.	Res.	Res.	SNB1			START1	FW1	PSIZE1		BER1	SER1	PG1	LOCK1
r/w					r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	rs

Bits 31:28 Reserved, must be kept at reset value

Bit 27 **CRCENDIE1**: Bank 1 end of CRC calculation interrupt enable bit

When CRCENDIE1 bit is set to '1', an interrupt is generated when the CRC computation has completed on bank 1. CRCENDIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when CRC computation complete on bank 1

1: interrupt generated when CRC computation complete on bank 1

Bit 26 **DBECCERRIE1**: Bank 1 ECC double detection error interrupt enable bit

When DBECCERRIE1 bit is set to '1', an interrupt is generated when an ECC double detection error occurs during a read operation from bank 1. DBECCERRIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when an ECC double detection error occurs on bank 1

1: interrupt generated if an ECC double detection error occurs on bank 1

Bit 25 **SNECCERRIE1**: Bank 1 ECC single correction error interrupt enable bit

When SNECCERRIE1 bit is set to '1', an interrupt is generated when an ECC single correction error occurs during a read operation from bank 1. SNECCERRIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when an ECC single correction error occurs on bank 1

1: interrupt generated when an ECC single correction error occurs on bank 1

Bit 24 **RDSERRIE1**: Bank 1 secure error interrupt enable bit

When RDSERRIE1 bit is set to '1', an interrupt is generated when a secure error (access to a secure protected address without the appropriate rights) occurs during a read operation from bank 1. RDSERRIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when a secure error occurs on bank 1

1: an interrupt is generated when a secure error occurs on bank 1

Bit 23 **RDPERRIE1**: Bank 1 read protection error interrupt enable bit

When RDPERRIE1 bit is set to '1', an interrupt is generated when a read protection error occurs (access to an address protected by PCROP) during a read operation from bank 1. RDPERRIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when a read protection error occurs on bank 1

1: an interrupt is generated when a read protection error occurs on bank 1

Bit 22 **OPERRIE1**: Bank 1 write/erase error interrupt enable bit

When OPERRIE1 bit is set to '1', an interrupt is generated when an error is detected during a write/erase operation to bank 1. OPERRIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when a write/erase error occurs on bank 1

1: interrupt generated when a write/erase error occurs on bank 1

Bit 21 **INCERRIE1**: Bank 1 inconsistency error interrupt enable bit

When INCERRIE1 bit is set to '1', an interrupt is generated when an inconsistency error occurs during a write operation to bank 1. INCERRIE1 can be programmed only when LOCK1 is set to '0'.

0: no interrupt generated when a inconsistency error occurs on bank 1

1: interrupt generated when a inconsistency error occurs on bank 1.

Bit 20 Reserved, must be kept at reset value

- Bit 19 **STRBERRIE1**: Bank 1 strobe error interrupt enable bit  
When STRBERRIE1 bit is set to '1', an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation to bank 1. STRBERRIE1 can be programmed only when LOCK1 is set to '0'.  
0: no interrupt generated when a strobe error occurs on bank 1  
1: interrupt generated when strobe error occurs on bank 1.
- Bit 18 **PGSERRIE1**: Bank 1 programming sequence error interrupt enable bit  
When PGSERRIE1 bit is set to '1', an interrupt is generated when a sequence error occurs during a program operation to bank 1. PGSERRIE1 can be programmed only when LOCK1 is set to '0'.  
0: no interrupt generated when a sequence error occurs on bank 1  
1: interrupt generated when sequence error occurs on bank 1.
- Bit 17 **WRPERRIE1**: Bank 1 write protection error interrupt enable bit  
When WRPERRIE1 bit is set to '1', an interrupt is generated when a protection error occurs during a program operation to bank 1. WRPERRIE1 can be programmed only when LOCK1 is set to '0'.  
0: no interrupt generated when a protection error occurs on bank 1  
1: interrupt generated when a protection error occurs on bank 1.
- Bit 16 **EOPIE1**: Bank 1 end-of-program interrupt control bit  
Setting EOPIE1 bit to '1' enables the generation of an interrupt at the end of a program operation to bank 1. EOPIE1 can be programmed only when LOCK1 is set to '0'.  
0: no interrupt generated at the end of a program operation to bank 1.  
1: interrupt enabled when at the end of a program operation to bank 1.
- Bit 15 **CRC\_EN**: Bank 1 CRC control bit  
Setting CRC\_EN bit to '1' enables the CRC calculation on bank 1. CRC\_EN does not start CRC calculation but enables CRC configuration through FLASH\_CRCCR1 register.  
When CRC calculation is performed on bank 1, it can only be disabled by setting CRC\_EN bit to '0'. Resetting CRC\_EN resets the content of FLASH\_CRCDATAR register.  
CRC\_EN can be programmed only when LOCK1 is set to '0'.
- Bits 14:11 Reserved, must be kept at reset value
- Bits 10:8 **SNB1**: Bank 1 sector erase selection number  
These bits are used to select the target sector for a sector erase operation. SNB1 can be programmed only when LOCK1 is set to '0'.  
000: sector 0 of bank 1  
001: sector 1 of bank 1  
...  
111: sector 7 of bank 1
- Bit 7 **START1**: Bank 1 bank or sector erase start control bit  
START1 bit is used to start a sector erase or a bank erase operation. START1 can be programmed only when LOCK1 is set to '0'.  
The Flash memory interface resets START1 when the corresponding operation has been acknowledged. The user application cannot access any Flash register until the operation has been acknowledged.

**Bit 6 FW1:** Bank 1 write forcing control bit

FW1 forces a write operation even if the write buffer is not full. FW1 can be programmed only when LOCK1 is set to '0'.

The Flash memory interface resets FW1 when the corresponding operation has been acknowledged. The user application cannot access any Flash register until the operation has been acknowledged.

Write forcing is effective only if the write buffer is not empty (in particular, FW1 will not start several write operations when the write operations are performed consecutively).

**Bits 5:4 PSIZE1:** Bank 1 program size

PSIZE1 selects the parallelism used by the Flash memory during write and erase operations to bank 1 (refer to [Section : Configuring the programming parameters](#) for details). PSIZE1 can be programmed only when LOCK1 is set to '0'.

00: programming executed with byte parallelism

01: programming executed with half-word parallelism

10: programming executed with word parallelism

11: programming executed with double word parallelism

**Bit 3 BER1:** Bank 1 erase request

Setting BER1 bit to '1' requests a bank erase operation on bank 1. BER1 can be programmed only when LOCK1 is set to '0'.

BER1 has a higher priority than SER1: if both are set, the Flash memory interface executes a bank erase (for more details, see [Section : Standard Flash bank erase](#)).

0: bank erase not requested on bank 1

1: bank erase requested on bank 1

**Bit 2 SER1:** Bank 1 sector erase request

Setting SER1 bit to '1' requests a sector erase on bank 1. SER1 can be programmed only when LOCK1 is set to '0'.

SER1 has a higher priority than BER1: if both are set, the Flash memory interface executes a sector erase (for more details, see [Section : Flash sector erase](#)).

0: sector erase not requested on bank 1

1: sector erase requested on bank 1

**Bit 1 PG1:** Bank 1 program enable bit

Setting PG1 bit to '1' enables write operations to bank 1. This allows preparing program operations even if a sector or bank erase is ongoing.

PG1 can be programmed only when LOCK1 is set to '0'. When PG1 is reset, the internal buffer is disabled for write operations to bank 1, and all the data stored in the buffer but not yet programmed are lost.

**Bit 0 LOCK1:** Bank 1 configuration lock bit

This bit locks the FLASH\_CR1 register.

When the FLASH\_CR1 register is unlocked, LOCK1 bit is automatically reset (see [Section : Configuring the programming parameters](#)). If a wrong sequence is executed, this bit remains locked until next system reset.

LOCK1 can be set by programming it to '1'. When set to '1', a new unlock sequence is mandatory to unlock it. When LOCK1 changes from '0' to '1', the other bits of FLASH\_CR1 register do not change.

0: FLASH\_CR1 register unlocked

1: FLASH\_CR1 register locked

### 3.5.5 FLASH status register for bank 1 (FLASH\_SR1)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CRCEND1	DBECCERR1	SNECCERR1	RDSERR1	RDPEERR1	OPERR1	INCERR1	Res.	STRBERR1	PGSERR1	WRPERR1	EOP1
				r	r	r	r	r	r	r		r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_BUSY1	QW1	WBNE1	BSY1
												r	r	r	r

Bits 31:28 Reserved, must be kept at reset value

Bit 27 **CRCEND1**: Bank 1 CRC-complete flag

CRCEND1 bit is raised when the CRC computation has completed on bank 1. An interrupt is generated if CRCENDIE1 is set to '1'. It is not necessary to reset CRCEND1 before restarting CRC computation. Writing '1' to CLR\_CRCEND1 bit in FLASH\_CCR1 register clears CRCEND1.

- 0: CRC computation not complete on bank 1
- 1: CRC computation complete on bank 1

Bit 26 **DBECCERR1**: Bank 1 ECC double detection error flag

DBECCERR1 flag is raised when an ECC double detection error occurs during a read operation from bank 1. An interrupt is generated if DBECCERRIE1 is set to '1'. Writing '1' to CLR\_DBECCERR1 bit in FLASH\_CCR1 register clears DBECCERR1.

- 0: no ECC double detection error occurs on bank 1
- 1: ECC double detection error occurs on bank 1

Bit 25 **SNECCERR1**: Bank 1 single correction error flag

SNECCERR1 flag is raised when an ECC single correction error occurs during a read operation from bank 1. An interrupt is generated if SNECCERRIE1 is set to '1'. Writing '1' to CLR\_SNECCERR1 bit in FLASH\_CCR1 register clears SNECCERR1.

- 0: no ECC single correction error occurs on bank 1
- 1: ECC single correction error occurs on bank 1

Bit 24 **RDSERR1**: Bank 1 secure error flag

RDSERR1 flag is raised when a secure error (access to a secure protected word without the appropriate rights) occurs on bank 1. An interrupt is generated if RDSERRIE1 is set to '1'. Writing '1' to CLR\_RDSERR1 bit in FLASH\_CCR1 register clears RDSERR1.

- 0: no secure error occurs on bank 1
- 1: a secure error occurs on bank 1

- Bit 23 **RDERR1**: Bank 1 read protection error flag  
RDERR1 flag is raised when a read protection error (access to a PCROP-protected word) occurs on bank 1. An interrupt is generated if RDERRIE1 is set to '1'. Writing '1' to CLR\_RDERR1 bit in FLASH\_CCR1 register clears RDERR1.  
0: no read protection error occurs on bank 1  
1: a read protection error occurs on bank 1
- Bit 22 **OPERR1**: Bank 1 write/erase error flag  
OPERR1 flag is raised when an error occurs during a write/erase to/from bank 1. An interrupt is generated if OPERRIE1 is set to '1'. Writing '1' to CLR\_OPERR1 bit in FLASH\_CCR1 register clears OPERR1.  
0: no write/erase error occurs on bank 1  
1: a write/erase error occurs on bank 1
- Bit 21 **INCERR1**: Bank 1 inconsistency error flag  
INCERR1 flag is raised when an inconsistency error occurs on bank 1. An interrupt is generated if INCERRIE1 is set to '1'. Writing '1' to CLR\_INCERR1 bit in the FLASH\_CCR1 register clears INCERR1.  
(refer to [Section 3.3.9: Flash interface error flags](#)).  
0: no inconsistency error occurs on bank 1  
1: an inconsistency error occurs on bank 1
- Bit 20 Reserved, must be kept at reset value
- Bit 19 **STRBERR1**: Bank 1 strobe error flag  
STRBERR1 flag is raised when a strobe error occurs on bank 1 (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE1 bit is set to '1'. Writing '1' to CLR\_STRBERR1 bit in FLASH\_CCR1 register clears STRBERR1.  
0: no strobe error occurs on bank 1  
1: a strobe error occurs on bank 1
- Bit 18 **PGSERR1**: Bank 1 programming sequence error flag  
PGSERR1 flag is raised when a sequence error occurs on bank 1. An interrupt is generated if the PGSERRIE1 bit is set to '1'. Writing '1' to CLR\_PGSERR1 bit in FLASH\_CCR1 register clears PGSERR1.  
0: no sequence error occurs on bank 1  
1: a sequence error occurs on bank 1
- Bit 17 **WRPERR1**: Bank 1 write protection error flag  
WRPERR1 flag is raised when a protection error occurs during a program operation to bank 1. An interrupt is also generated if the EOPIE1 is set to '1'. Writing '1' to CLR\_EOP1 bit in FLASH\_CCR1 register clears WRPERR1.  
0: no protection error occurs on bank 1  
1: a protection error occurs on bank 1
- Bit 16 **EOP1**: Bank 1 end-of-program flag  
EOP1 flag is set when a programming operation to bank 1 completes. An interrupt is generated if the EOPIE1 is set to '1'. It is not necessary to reset EOP1 before starting a new operation. EOP1 bit is cleared by writing '1' to CLR\_EOP1 bit in FLASH\_CCR1 register.  
0: no programming operation completed on bank 1  
1: a programming operation completed on bank 1
- Bits 15:4 Reserved, must be kept at reset value

**Bit 3 CRC\_BUSY1:** Bank 1 CRC busy flag

CRC\_BUSY1 flag is set when a CRC calculation is ongoing on bank 1. This bit cannot be forced to '0'. The user must wait until the CRC calculation has completed or disable CRC computation on bank 1.

0: no CRC calculation ongoing on bank 1

1: CRC calculation ongoing on bank 1

**Bit 2 QW1:** Bank 1 wait queue flag

QW1 flag is set when a program operation to bank 1 is in the waiting queue. It is not possible to know what type of programming operation is in the queue. When all program operations have been executed and thus removed from the waiting queue, this flag is reset by hardware. This bit cannot be forced to '0'. It is reset after a deterministic time if no other operations are requested.

0: no program operations waiting in the operation queue of bank 1

1: at least one programming operation is waiting in the operation queue of bank 1

**Bit 1 WBNE1:** Bank 1 write buffer not empty flag

WBNE1 flag is set when bank 1 write buffer is not empty and the Flash memory interface is waiting for new data to complete it.

WBNE1 is reset by hardware each time the write buffer is emptied. This happens when one of the following event occurs:

- the write buffer is full
- the user forces the write operation
- an error that involves data loss
- the write operation has been disabled.

This bit cannot be forced to '0'. To reset it, clear the write buffer by performing any of the above listed actions.

0: write buffer of bank 1 empty

1: write buffer of bank 1 waiting data to complete

**Bit 0 BSY1:** Bank 1 ongoing program flag

BSY1 flag is set when a program operation to bank 1 is ongoing. It is not possible to know what type of program operation is ongoing.

BSY1 cannot be forced to '0'. It is reset by hardware when the operation completes, provided no other program operation starts.

0: no programming operation executing on bank 1

1: programming operation executing on bank 1.

### 3.5.6 FLASH clear control register for bank 1 (FLASH\_CCR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CLR_CRCEND1	CLR_DBECCERR1	CLR_SNECCERR1	CLR_RDSERR1	CLR_RDPERR1	CLR_OPERR1	CLR_INCERR1	Res.	CLR_STRBERR1	CLR_PGSERR1	CLR_WRPERR1	CLR_EOP1
				w	w	w	w	w	w	w		w	w	w	w

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:28 Reserved, must be kept at reset value

Bit 27 **CLR\_CRCEND1**: Bank 1 CRCEND1 flag clear bit

Setting this bit to '1' resets to '0' CRCEND1 flag of FLASH\_SR1 register.

Bit 26 **CLR\_DBECCERR1**: Bank 1 DBECCERR1 flag clear bit

Setting this bit to '1' resets to '0' DBECCERR1 flag of FLASH\_SR1 register. If the SNECCERR1 flag of FLASH\_SR1 register is set to '0', FLASH\_ECC\_FA1R register are reset to '0' as well.

Bit 25 **CLR\_SNECCERR1**: Bank 1 SNECCERR1 flag clear bit

Setting this bit to '1' resets to '0' SNECCERR1 flag of FLASH\_SR1 register. If the DBECCERR1 flag of FLASH\_SR1 register is set to '0', FLASH\_ECC\_FA1R register are reset to '0' as well.

Bit 24 **CLR\_RDSERR1**: Bank 1 RDSERR1 flag clear bit

Setting this bit to '1' resets to '0' RDSERR1 flag of FLASH\_SR1 register.

Bit 23 **CLR\_RDPERR1**: Bank 1 RDPERR1 flag clear bit

Setting this bit to '1' resets to '0' RDPERR1 flag of FLASH\_SR1 register.

Bit 22 **CLR\_OPERR1**: Bank 1 OPERR1 flag clear bit

Setting this bit to '1' resets to '0' OPERR1 flag of FLASH\_SR1 register.

Bit 21 **CLR\_INCERR1**: Bank 1 INCERR1 flag clear bit

Setting this bit to '1' resets to '0' INCERR1 flag of FLASH\_SR1 register.

Bit 20 Reserved, must be kept at reset value

Bit 19 **CLR\_STRBERR1**: Bank 1 STRBERR1 flag clear bit

Setting this bit to '1' resets to '0' STRBERR1 flag of FLASH\_SR1 register.

Bit 18 **CLR\_PGSERR1**: Bank 1 PGSERR1 flag clear bit

Setting this bit to '1' resets to '0' PGSERR1 flag of FLASH\_SR1 register.

Bit 17 **CLR\_WRPERR1**: Bank 1 WRPERR1 flag clear bit  
 Setting this bit to '1' resets to '0' WRPERR1 flag of FLASH\_SR1 register.

Bit 16 **CLR\_EOP1**: Bank 1 EOP1 flag clear bit  
 Setting this bit to '1' resets to '0' EOP1 flag of FLASH\_SR1 register.

Bits 15:0 Reserved, must be kept at reset value

### 3.5.7 FLASH option control register (FLASH\_OPTCR)

Address offset: 0x018 or 0x118

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK	OPTCHANGEERRIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MER	Res.	OPTSTART	OPTLOCK
												w		rw	rs

Bit 31 **SWAP\_BANK**: Bank swapping configuration bit  
 SWAP\_BANK controls whether the bank 1 and bank 2 are swapped or not. After option byte loading, this bit is loaded with the SWAP\_BANK\_OPT bit of FLASH\_OPTSR\_CUR register. When the FLASH\_OPTCR register is unlocked (OPTLOCK = '0'), the master can modify SWAP\_BANK to swap/unswap user Flash memory banks (see [Section 3.3.13: Flash bank swapping](#)).  
 0: bank 1 and bank 2 not swapped  
 1: bank 1 and bank 2 swapped.

Bit 30 **OPTCHANGEERRIE**: Option byte change error interrupt enable bit  
 OPTCHANGEERRIE bit controls if an interrupt has to be generated when an error occurs during an option byte change.  
 0: no interrupt is generated when an error occurs during an option byte change  
 1: an interrupt is generated when an error occurs during an option byte change.

Bits 29:5 Reserved, must be kept at reset value

Bit 4 **MER**: Flash mass erase enable bit  
 To program MER bit, FLASH\_CR1, FLASH\_CR2 and FLASH\_OPTCR registers must have been previously unlocked.  
 Programming MER bit to '1' automatically sets BER1, BER2, START1 and START2 to '1'. This allows to mass erase both banks simultaneously.

Bits 3:2 Reserved, must be kept at reset value

Bit 1 **OPTSTART**: Option byte start change option configuration bit

OPTSTART triggers an option byte change operation. The user can set OPTSTART only when the OPTLOCK bit is set to '0'. The Flash memory interface resets OPTSTART when the option byte change operation has been acknowledged.

The user application cannot access any Flash register until the operation has been acknowledged.

Before setting this bit, the user has to write the required values in the FLASH\_XXX\_PRG registers. The FLASH\_XXX\_PRG registers will be locked until the option byte change operation has been executed in Flash memory.

It is not possible to start an option byte change operation if a CRC calculation is ongoing on bank 1 or bank 2: trying to set OPTSTART when CRC\_BUSY1/2 of FLASH\_SR1/2 register is set has no effect; the option byte change does not start and no error is generated.

Bit 0 **OPTLOCK**: FLASH\_OPTCR lock option configuration bit

The OPTLOCK bit locks the FLASH\_OPTCR register. When FLASH\_OPTCR is unlocked OPTLOCK is automatically reset (see [Section : Configuring the programming parameters](#)). If a wrong sequence is executed, this bit remains locked until next system reset.

It is possible to set OPTLOCK by programming it to '1'. When set to '1', a new unlock sequence is mandatory to unlock it. When OPTLOCK changes from '0' to '1', the other bits of FLASH\_OPTCR register do not change.

0: FLASH\_OPTCR register unlocked

1: FLASH\_OPTCR register locked.

### 3.5.8 FLASH option status register (current value) (FLASH\_OPTSR\_CUR)

Address offset: 0x01C or 0x11C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK_OPT	OPTCHANGEERR	IO_HSLV	PERSO_OK	RSS2	RSS1	Res.	Res.	Res.	Res.	SECURITY	ST_RAM_SIZE		FZ_IWDG_SDBY	FZ_IWDG_STOP	Res.
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	r	r	r	r	r	r	r	r	r	r	r	r		r

- Bit 31 **SWAP\_BANK\_OPT**: Bank swapping option status bit  
SWAP\_BANK\_OPT reflects the value of the corresponding option bit that configures the default value for bank 1/2 swapping.  
0: after boot loading, no swap for user sectors  
1: after boot loading, user sectors swapped.
- Bit 30 **OPTCHANGEERR**: Option byte change error flag  
OPTCHANGEERR flag indicates that an error occurred during an option byte change operation. When OPTCHANGEERR is set to '1', the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTCHANGEERRIE bit of FLASH\_OPTCR register is set to '1'.  
Writing '1' to CLR\_OPTCHANGEERR of register FLASH\_OPTCCR clears OPTCHANGEERR.  
0: no option byte change errors occurred  
1: one or more errors occurred during an option byte change operation.
- Bit 29 **IO\_HSLV**: I/O high-speed at low-voltage status bit (PRODUCT\_BELOW\_25V)  
This bit indicates that the product operates below 2.5 V.  
0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled  
1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed
- Bit 28 **PERSO\_OK**: Device personalization status bit  
PERSO\_OK indicates that the device has been personalized.
- Bit 27 **RSS2**: User option bit 2  
RSS2 is used for ST development code (RSS / bootloader).
- Bit 26 **RSS1**: User option bit 1  
RSS1 is used for ST development code (RSS / bootloader).
- Bits 25: 22 Reserved, must be kept at reset value
- Bit 21 **SECURITY**: Security enable option status bit  
0: Security feature disabled  
1: Security feature enabled.
- Bits 20:19 **ST\_RAM\_SIZE**: DTCM RAM size option status  
00: 2 Kbytes  
01: 4 Kbytes  
10: 8 Kbytes  
11: 16 Kbytes  
*Note: This bitfield is effective only when the security is enabled (SECURITY = '1').*
- Bit 18 **FZ\_IWDG\_SDBY**: IWDG Standby mode freeze option status bit  
This bit reflects the freeze status of the IWDG\_FZ\_STOP option bit..  
0: Independent watchdog frozen in Standby mode  
1: Independent watchdog running in Standby mode.
- Bit 17 **FZ\_IWDG\_STOP**: IWDG Stop mode freeze option status bit  
This bit reflects the freeze status of the IWDG\_FZ\_STANDBY option bit.  
0: Independent watchdog frozen in Stop mode  
1: Independent watchdog running in Stop mode.
- Bit 16 Reserved, must be kept at reset value

- Bits 15:8 **RDP**: Readout protection level option status byte  
For more information about the readout protection level (refer to [Section : RDP \(Readout protection\)](#)). Three different levels are available:  
0xAA: protection level 0  
0xCC: protection level 2  
others values: protection level 1.
- Bit 7 **nRST\_STBY\_D1**: D1 DStandby entry reset option status bit  
0: a reset is generated when entering DStandby mode on D1 domain  
1: no reset generated
- Bit 6 **nRST\_STOP\_D1**: D1 DStop entry reset option status bit  
0: a reset is generated when entering DStop mode on D1 domain  
1: no reset generated
- Bit 5 Reserved, must be kept at reset value
- Bit 4 **IWDG1\_HW**: IWDG1 control option status bit  
0: IWDG1 is controlled by software  
1: IWDG1 watchdog is controller by hardware.
- Bits 3:2 **BOR\_LEV**: Brownout level option status bit  
These option bits are used to define the power level that generate a system reset.  
00: the reset level is set to 2.1 V  
01: the reset is set to 2.4 V  
10: the reset is set to 2.7 V  
11: the reset level is set to 2.1 V (as 00 configuration).
- Bit 1 Reserved, must be kept at reset value
- Bit 0 **OPT\_BUSY**: Option byte change ongoing flag  
OPT\_BUSY indicates if an option byte change is ongoing. When this bit is set to '1', the Flash memory interface is performing an option change and it is not possible to modify any Flash register.  
0: no option byte change ongoing  
1: an option byte change ongoing and all write accesses to Flash registers are blocked until the option byte change completes.

### 3.5.9 FLASH option status register (value to program) (FLASH\_OPTSR\_PRG)

Address offset: 0x020 or 0x120

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWAP_BANK_OPT	Res.	IO_HSLV	Res.	RSS2	RSS1	Res.	Res.	Res.	Res.	SECURITY	ST_RAM_SIZE		FZ_IWDG_SDBY	FZ_IWDG_STOP	Res.

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w		

- Bit 31 **SWAP\_BANK\_OPT**: Bank swapping option configuration bit  
 SWAP\_BANK\_OPT option bit is used to configure the default value for bank 1/2 swapping.  
 0: after boot loading, no swap for user sectors  
 1: after boot loading, user sectors swapped.
- Bit 30 Reserved, must be kept at reset value
- Bit 29 **IO\_HSLV**: I/O high-speed at low-voltage (PRODUCT\_BELOW\_25V)  
 This bit indicates that the product operates below 2.5 V. It must be set only if the product supply voltage is below 2.5 V.  
 0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled  
 1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed
- Bit 28 Reserved, must be kept at reset value
- Bit 27 **RSS2**: User option configuration bit 2  
**RSS2** is used for ST development code (RSS / bootloader). Modifying this bit has no effect.
- Bit 26 **RSS1**: User option configuration bit 1  
**RSS1** is used for ST development code (RSS / bootloader). Modifying this bit has no effect.
- Bits 25: 22 Reserved, must be kept at reset value

Bit 21 **SECURITY**: Security option configuration bit

The SECURITY bit enables the security feature at device level during an option byte change. The change will be taken into account at next power-on reset.

Once it is enabled, the security feature can be disabled if no areas are protected by PCROP or secure mode. If there are secure or PCROP protected areas, perform a level regression (from level 1 to 0) and set all the bits to unprotect secure areas and PCROP areas (see [Section 3.3.12: Protection mechanisms](#)).

0: Security feature disabled  
1: Security feature enabled.

Bits 20:19 **ST\_RAM\_SIZE**: DTCM size select option configuration bits

ST\_RAM\_SIZE bits are used during an option byte change to set the size of DTCM RAM to be protected.

00: 2 Kbytes  
01: 4 Kbytes  
10: 8 Kbytes  
11: 16 Kbytes

*Note: This bitfield is effective only when the security is enabled (SECURITY = '1').*

Bit 18 **FZ\_IWDG\_SDBY**: IWDG Standby mode freeze option configuration bit

FZ\_IWDG\_SDBY is used during option byte change to select if the independent watchdog is frozen in Standby mode.

0: Independent watchdog frozen in Standby mode  
1: Independent watchdog running in Standby mode.

Bit 17 **FZ\_IWDG\_STOP**: IWDG Stop mode freeze option configuration bit

FZ\_IWDG\_STOP is used during option change to select if the independent watchdog is frozen in Stop mode.

0: Independent watchdog frozen in Stop mode  
1: Independent watchdog running in Stop mode.

Bit 16 Reserved, must be kept at reset value

Bits 15:8 **RDP**: Readout protection level option configuration byte

RDP bits are used to change the readout protection level. This change is possible only when the current protection level is different from level 2 (see [Section : RDP \(Readout protection\)](#)).

The possible configurations are:

0xAA: to set the protection level 0  
0xCC: to set the protection level 2  
all others values: to set the protection level 1.

Bit 7 **nRST\_STBY\_D1**: Option byte erase after D1 DStandby option configuration bit

nRST\_STBY\_D1 is used during option byte change. When it is set to '1', option bytes are erased when entering DStandby mode on D1 domain.

0: Option bytes erased when entering DStandby mode on D1 domain  
1: Option bytes Option bytes not erased when entering DStandby mode on D1 domain

Bit 6 **nRST\_STOP\_D1**: Option byte erase after D1 DStop option configuration bit

nRST\_STOP\_D1 is used during option byte change. When it is set to '1', the options bytes are erased when entering DStop mode on D1 domain.

0: Option bytes erased when entering DStop mode on D1 domain  
1: Option bytes Option bytes not erased when entering DStop mode on D1 domain

Bit 5 Reserved, must be kept at reset value

Bit 4 **IWDG1\_HW**: IWDG1 option configuration bit  
 IWDG1\_HW option bit is used to select if IWDG1 independent watchdog has to be controlled by hardware or by software.  
 0: IWDG1 controlled by software  
 1: IWDG1 controlled by hardware.

Bits 3:2 **BOR\_LEV**: BOR reset level option configuration bits  
 FLASH\_OPTSR\_PRG are used to change the BOR\_LEV option byte. To modify this option, the user must program BOR\_LEV to the required configuration before starting an option byte change. The possible configurations are:  
 00 and 11: the reset level is set to 2.1 V  
 01: the reset is set to 2.4 V  
 10: the reset is set to 2.7 V

Bits 1:0 Reserved, must be kept at reset value

### 3.5.10 FLASH option clear control register (FLASH\_OPTCCR)

Address offset: 0x024 or 0x124

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CLR_OPTCHANGEERR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	w														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value

Bit 30 **CLR\_OPTCHANGEERR**: OPTCHANGEERR reset bit  
 FLASH\_OPTCCR is used to reset the OPTCHANGEERR flag of FLASH\_OPTSR\_CUR register. FLASH\_OPTCCR is write-only.  
 It is reset by programming it to '1'.

Bits 29:0 Reserved, must be kept at reset value

### 3.5.11 FLASH protection address for bank 1 (current value) (FLASH\_PRAR\_CUR1)

Address offset: 0x028

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP1	Res.	Res.	Res.	PROT_AREA_END1											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PROT_AREA_START1											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMEP1**: Bank 1 PCROP protected erase enable option status bit  
 If DMEP1 is set to '1', the PCROP protected areas are erased when a protection level regression (change from level 1 to 0) occurs ([Section : PCROP area \(proprietary code readout protection, execute-only area\)](#) and [Section : Standard Flash bank erase](#)).

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **PROT\_AREA\_END1**: Bank 1 highest PCROP protected address  
 These bits contain the last address protected by PCROP in bank 1.  
 If this address is equal to PROT\_AREA\_START1, the whole bank 1 is PCROP protected.  
 If this address is lower than PROT\_AREA\_START1, no protection is set on bank 1.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **PROT\_AREA\_START1**: Bank 1 lowest PCROP protected address  
 These bits contain the first address protected by PCROP in bank 1.  
 If this address is equal to PROT\_AREA\_END1, the whole bank 1 is PCROP protected.  
 If this address is higher than PROT\_AREA\_END1, no protection is set on bank 1.

### 3.5.12 FLASH protection address for bank 1 (value to program) (FLASH\_PRAR\_PRG1)

Address offset: 0x02C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
DMEP1	Res.	Res.	Res.	PROT_AREA_END1												
	r/w			r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Res.	Res.	Res.	Res.	PROT_AREA_START1											
				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

- Bit 31 **DMEP1**: Bank 1 PCROP protected erase enable option configuration bit  
If DMEP1 is set to '1', the PCROP protected areas are erased when a protection level regression (change from level 1 to 0) or a bank 1 erase occurs ([Section : PCROP area \(proprietary code readout protection, execute-only area\)](#)).
- Bits 30:28 Reserved, must be kept at reset value
- Bits 27:16 **PROT\_AREA\_END1**: Bank 1 highest PCROP protected address configuration  
These bits allow configuring the last PCROP protected address in bank 1.
- Bits 15:12 Reserved, must be kept at reset value
- Bits 11:0 **PROT\_AREA\_START1**: Bank 1 lowest PCROP protected address configuration  
These bits allow configuring the first PCROP protected address in bank 1.

### 3.5.13 FLASH secure address for bank 1 (current value) (FLASH\_SCAR\_CUR1)

Address offset: 0x030

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
DMES1	Res.	Res.	Res.	SEC_AREA_END1												
	r			r	r	r	r	r	r	r	r	r	r	r	r	r
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Res.	Res.	Res.	Res.	SEC_AREA_START1											
				r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMES1**: Bank 1 secure protected erase enable option status bit  
 If DMES1 is set to '1', the secure protected areas are erased when a protection level regression (change from level 1 to 0) occurs ([Section : Secure area](#) and [Section : Standard Flash bank erase](#)).

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **SEC\_AREA\_END1**: Bank 1 highest secure protected address  
 These bits contain the last secure protected address in bank 1.  
 If this address is equal to SEC\_AREA\_START1, the whole bank 1 is secure protected.  
 If this address is lower than SEC\_AREA\_START1, no protection is set on bank 1.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **SEC\_AREA\_START1**: Bank 1 lowest secure protected address  
 These bits contain the first secure protected address in bank 1.  
 If this address is equal to SEC\_AREA\_END1, the whole bank 1 is secure protected.  
 If this address is higher than SEC\_AREA\_END1, no protection is set on bank 1.

### 3.5.14 FLASH secure address for bank 1 (value to program) (FLASH\_SCAR\_PRG1)

Address offset: 0x034

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES1	Res.	Res.	Res.	SEC_AREA_END1											
	r/w			r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	SEC_AREA_START1											
				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bit 31 **DMES1**: Bank 1 secure protected erase enable option configuration bit  
 If DMES1 is set to '1', the secure protected areas are erased when a protection level regression (change from level 1 to 0) or a bank 1 erase occurs ([Section : Secure area](#)).

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **SEC\_AREA\_END1**: Bank 1 highest secure protected address configuration  
 These bit allow configuring the last secure protected address in bank 1.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **SEC\_AREA\_START1**: Bank 1 lowest secure protected address configuration  
 These bit allow configuring the first secure protected address in bank 1.

### 3.5.15 FLASH write sector protection for bank 1 (current value) (FLASH\_WPSN\_CUR1R)

Address offset: 0x038

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPSn1							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **WRPSn1**: Bank 1 sector write protection option status byte

Each FLASH\_WPSN\_CUR1R bit reflects the write protection status of the corresponding bank 1 sector (see [Section : Sector write protection](#)).

### 3.5.16 FLASH write sector protection for bank 1 (value to program) (FLASH\_WPSN\_PRG1R)

Address offset: 0x03C

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPSn1							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **WRPSn1**: Bank 1 sector write protection configuration byte

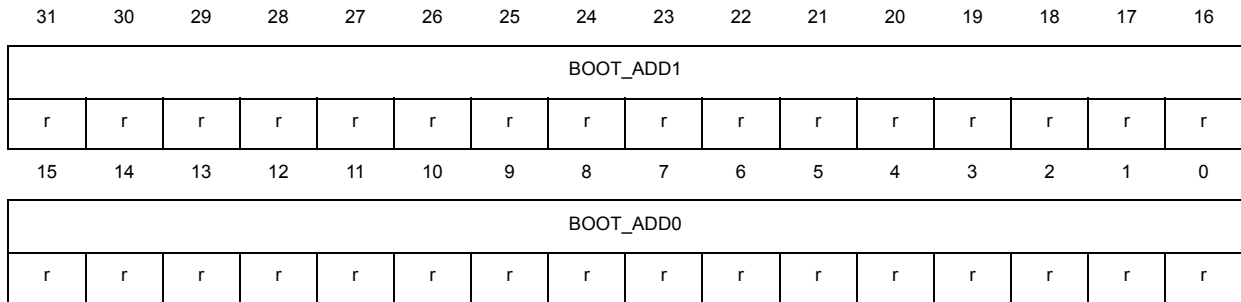

Setting WRPSn1 bit to '0' allows write protecting the corresponding bank 1 sector (see [Section : Sector write protection](#)).

### 3.5.17 FLASH register with boot address (current value) (FLASH\_BOOT\_CURR)

Address offset: 0x040

Reset value: 0xXXXX XXXX

Bits 31:16 BOOT\_ADD1: Boot address 1

These bits reflect the MSB of the boot address when BOOT pin is high.

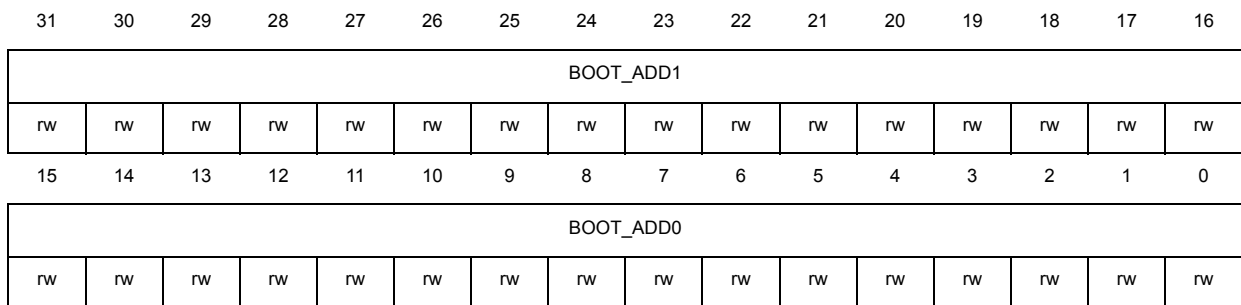

Bits 15:0 BOOT\_ADD0: Boot address 0

These bits reflect the MSB of the boot address when BOOT pin is low.

### 3.5.18 FLASH register with boot address (value to program) (FLASH\_BOOT\_PRGR)

Address offset: 0x044

Reset value: 0xXXXX XXXX

Bits 31:16 BOOT\_ADD1: Boot address 1 configuration

These bits allow configuring the MSB of the boot address when BOOT pin is high.

Bits 15:0 BOOT\_ADD1: Boot address 0 configuration

These bits allow configuring the MSB of the boot address when BOOT pin is low.

### 3.5.19 FLASH CRC control register for bank 1 (FLASH\_CRCCR1)

Address offset: 0x050

Reset value: 0x001C 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_BURST		Res.	Res.	CLEAN_CRC	START_CRC
										r/w	r/w			w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CLEAN_SECT	ADD_SECT	CRC_BY_SECT	ALL_BANK	Res.	Res.	Res.	Res.	CRC_SECT		
					w	w	r/w	w					r/w	r/w	r/w

Bits 31:22 Reserved, must be kept at reset value

Bits 21:20 **CRC\_BURST: Bank 1** CRC burst size

CRC\_BURST bits set the size of the bursts that are generated by the CRC calculation unit.

00: every burst has a size of 4 Flash words

01: every burst has a size of 16 Flash words

10: every burst has a size of 64 Flash words

11: every burst has a size of 256 Flash words

Bits 19:18 Reserved, must be kept at reset value

Bit 17 **CLEAN\_CRC:** Bank 1 CRC clear bit

Setting CLEAN\_CRC to '1' clears the current CRC result stored in the FLASH\_CRCDATAR register.

Bit 16 **START\_CRC:** Bank 1 CRC start bit

START\_CRC bit triggers a CRC calculation on bank 1 using the current configuration. It is not possible to start a CRC calculation when an option byte change operation is ongoing because all write accesses to Flash registers are put on hold until the option byte change operation has completed.

Bits 15:13 Reserved, must be kept at reset value

Bits 12:11 Reserved, must be kept at reset value

Bit 10 **CLEAN\_SECT:** Bank 1 CRC sector list clear bit

Setting CLEAN\_SECT to '1' clears the list of sectors on which the CRC is calculated.

Bit 9 **ADD\_SECT:** Bank 1 CRC sector select bit

Setting ADD\_SECT to '1' adds the sector whose number is CRC\_SECT to the list of sectors on which the CRC is calculated.

Bit 8 **CRC\_BY\_SECT**: Bank 1 CRC sector mode select bit

When CRC\_BY\_SECT is set to '1', the CRC calculation is performed at sector level, on the sectors selected by CRC\_SECT or on all banks if ALL\_BANK bit is set.

When CRC\_BY\_SECT is reset to '0', the CRC calculation is performed on all addresses between CRC\_START\_ADDR and CRC\_END\_ADDR.

Bit 7 **ALL\_BANK**: Bank 1 CRC select bit

When ALL\_BANK is set to '1', all bank 1 user sectors are added to list of sectors on which the CRC is calculated.

Bits 6:3 Reserved, must be kept at reset value

Bits 2:0 **CRC\_SECT**: Bank 1 CRC sector number

CRC\_SECT is used to select one or more sectors to be added to CRC calculation. The CRC can be computed either between two addresses (start address and end address) or on a list of sectors. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC\_SECT and then setting to '1' ADD\_SECT.

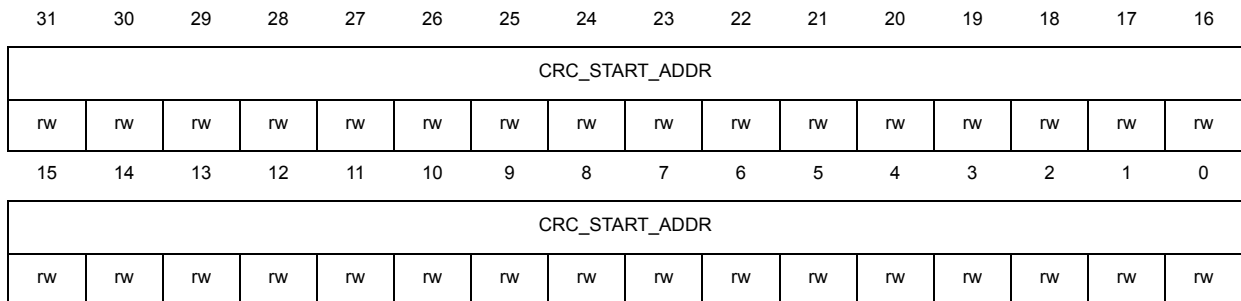

The list of sectors can be erased either by setting CLEAN\_SECT bit or by disabling the CRC computation. To know the number of each sector, refer to the description of SNB1 bits in FLASH\_CR register (see [Section 3.5.4: FLASH control register for bank 1 \(FLASH\\_CR1\)](#)).

CRC\_SECT can be set only when CRC\_EN of FLASH\_CR register is set to '1'.

### 3.5.20 FLASH CRC start address register for bank 1 (FLASH\_CRCSADD1R)

Address offset: 0x054

Reset value: 0x0000 0000

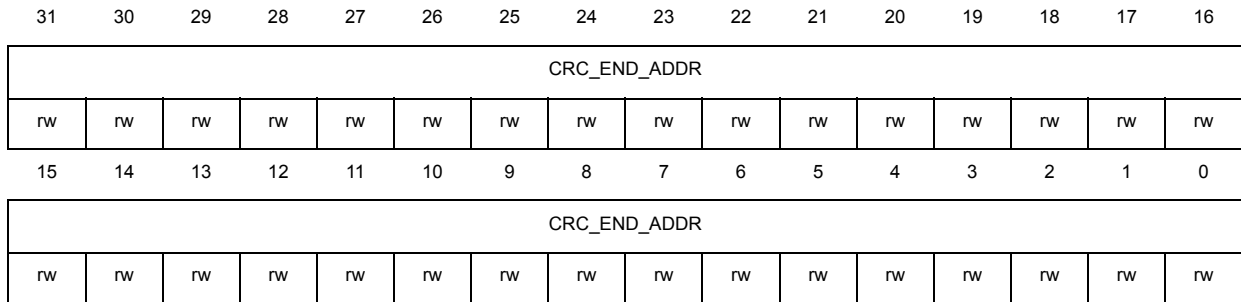

Bits 31:0 **CRC\_START\_ADDR**: CRC start address on bank 1

CRC\_START\_ADDR is used when CRC\_BY\_SECT is '0'. It must be programmed to the start address of the bank 1 memory area on which the CRC calculation is performed.

### 3.5.21 FLASH CRC end address register for bank 1 (FLASH\_CRCEADD1R)

Address offset: 0x058

Reset value: 0x0000 0000

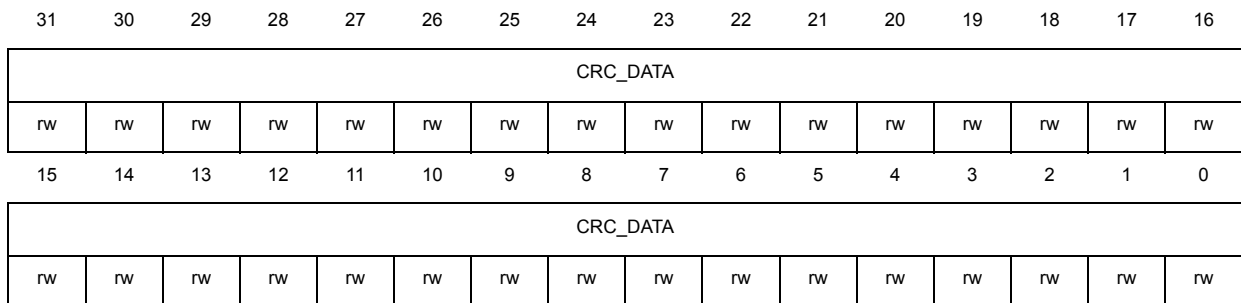

Bits 31:0 **CRC\_END\_ADDR**: CRC end address on bank 1

CRC\_END\_ADDR is used when CRC\_BY\_SECT is '0'. It must be programmed to the end address of the bank 1 memory area on which the CRC calculation is performed

### 3.5.22 FLASH CRC data register (FLASH\_CRCDATAR)

Address offset: 0x05C or 0x15C

Reset value: 0x0000 0000

Bits 31:0 **CRC\_DATA**: CRC result

CRC\_DATA contain the result of the CRC calculation.

### 3.5.23 FLASH ECC fail address for bank 1 (FLASH\_ECC\_FA1R)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FAIL_ECC_ADDR1														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value

Bits 14:0 **FAIL\_ECC\_ADDR1**: Bank 1 ECC error address

When an ECC error occurs (both for single correction or double detection) during a read operation from bank 1, the FAIL\_ECC\_ADDR1 bitfield contains the address that generated the error.

FAIL\_ECC\_ADDR1 is reset when the flag error in the FLASH\_SR1 register (CLR\_SNECCERR1 or CLR\_DBECCERR1) is reset.

The Flash memory interface programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.

### 3.5.24 FLASH key register for bank 2 (FLASH\_KEYR2)

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEYR2															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEYR2															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEYR2**: Bank 2 access configuration unlock key

FLASH\_KEYR2 is a write-only register. The following values must be programmed consecutively to unlock FLASH\_CR2 register and allow programming/erasing it:

- a) 1stkey = 0x4567 0123
- b) 2ndkey = 0xCDEF 89AB

For more details, see [Section : Configuring the programming parameters](#).

### 3.5.25 FLASH control register for bank 2 (FLASH\_CR2)

Address offset: 0x10C

Reset value: 0x0000 0031

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CRCENDIE2	DBECCERRIE2	SNECCERRIE2	RDSERRIE2	RDPERRIE2	OPERRIE2	INCERRIE2	Res.	STRBERRIE2	PGSERRIE2	WRPERRIE2	EOPIE2
				r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_EN	Res.	Res.	Res.	Res.	SNB2			START2	FW2	PSIZE2		BER2	SER2	PG2	LOCK2
r/w					r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	rs

Bits 31:28 Reserved, must be kept at reset value

Bit 27 **CRCENDIE2**: Bank 2 end of CRC calculation interrupt enable bit

When CRCENDIE2 bit is set to '1', an interrupt is generated when the CRC computation has completed on bank 2. CRCENDIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when CRC computation complete on bank 2  
 1: interrupt generated when CRC computation complete on bank 2

Bit 26 **DBECCERRIE2**: Bank 2 ECC double detection error interrupt enable bit

When DBECCERRIE2 bit is set to '1', an interrupt is generated when an ECC double detection error occurs during a read operation from bank 2. DBECCERRIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when an ECC double detection error occurs on bank 2  
 1: interrupt generated if an ECC double detection error occurs on bank 2

Bit 25 **SNECCERRIE2**: Bank 2 ECC single correction error interrupt enable bit

When SNECCERRIE2 bit is set to '1', an interrupt is generated when an ECC single correction error occurs during a read operation from bank 2. SNECCERRIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when an ECC single correction error occurs on bank 2  
 1: interrupt generated when an ECC single correction error occurs on bank 2

Bit 24 **RDSERRIE2**: Bank 2 secure error interrupt enable bit

When RDSERRIE2 bit is set to '1', an interrupt is generated when a secure error (access to a secure protected address without the appropriate rights) occurs during a read operation from bank 2. RDSERRIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when a secure error occurs on bank 2  
 1: an interrupt is generated when a secure error occurs on bank 2

Bit 23 **RDPERRIE2**: Bank 2 read protection error interrupt enable bit

When RDPERRIE2 bit is set to '1', an interrupt is generated when a read protection error occurs (access to an address protected by PCROP) during a read operation from bank 2. RDPERRIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when a read protection error occurs on bank 2  
 1: an interrupt is generated when a read protection error occurs on bank 2

Bit 22 **OPERRIE2**: Bank 2 write/erase error interrupt enable bit

When OPERRIE2 bit is set to '1', an interrupt is generated when an error is detected during a write/erase operation to bank 2. OPERRIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when a write/erase error occurs on bank 2  
 1: interrupt generated when a write/erase error occurs on bank 2

Bit 21 **INCERRIE2**: Bank 2 inconsistency error interrupt enable bit

When INCERRIE2 bit is set to '1', an interrupt is generated when an inconsistency error occurs during a write operation to bank 2. INCERRIE2 can be programmed only when LOCK2 is set to '0'.

0: no interrupt generated when a inconsistency error occurs on bank 2  
 1: interrupt generated when a inconsistency error occurs on bank 2

Bit 20 Reserved, must be kept at reset value

- Bit 19 **STRBERRIE2**: Bank 2 strobe error interrupt enable bit  
 When STRBERRIE2 bit is set to '1', an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation to bank 2. STRBERRIE2 can be programmed only when LOCK2 is set to '0'.  
 0: no interrupt generated when a strobe error occurs on bank 2  
 1: interrupt generated when strobe error occurs on bank 2
- Bit 18 **PGSERRIE2**: Bank 2 programming sequence error interrupt enable bit  
 When PGSERRIE2 bit is set to '1', an interrupt is generated when a sequence error occurs during a program operation to bank 2. PGSERRIE2 can be programmed only when LOCK2 is set to '0'.  
 0: no interrupt generated when a sequence error occurs on bank 2  
 1: interrupt generated when sequence error occurs on bank 2
- Bit 17 **WRPERRIE2**: Bank 2 write protection error interrupt enable bit  
 When WRPERRIE2 bit is set to '1', an interrupt is generated when a protection error occurs during a program operation to bank 2. WRPERRIE2 can be programmed only when LOCK2 is set to '0'.  
 0: no interrupt generated when a protection error occurs on bank 2  
 1: interrupt generated when a protection error occurs on bank 2
- Bit 16 **EOPIE2**: Bank 2 end-of-program interrupt control bit  
 Setting EOPIE2 bit to '1' enables the generation of an interrupt at the end of a program operation to bank 2. EOPIE2 can be programmed only when LOCK2 is set to '0'.  
 0: no interrupt generated at the end of a program operation to bank 2.  
 1: interrupt enabled when at the end of a program operation to bank 2
- Bit 15 **CRC\_EN**: Bank 2 CRC control bit  
 Setting CRC\_EN bit to '1' enables the CRC calculation on bank 2. CRC\_EN does not start CRC calculation but enables CRC configuration through FLASH\_CRCCR2 register.  
 When CRC calculation is performed on bank 2, it can only be disabled by setting CRC\_EN bit to '0'. Resetting CRC\_EN resets the content of FLASH\_CRCDATAR register.  
 CRC\_EN can be programmed only when LOCK2 is set to '0'.
- Bits 14:11 Reserved, must be kept at reset value
- Bits 10:8 **SNB2**: Bank 2 sector erase selection number  
 These bits are used to select the target sector for a sector erase operation. SNB2 can be programmed only when LOCK2 is set to '0'. When the most significant bit is set to '1', the third bit is used to select between ICP sectors and Option sectors. 000 0000: sector 0 of bank 2  
 000 0001: sector 1 of bank 2  
 ...  
 000 0111: sector 7 of bank 2  
 000 1000 to 011 1111: reserved (it's not possible to set this configuration)  
 ...  
 011 1111: reserved (it's not possible to set this configuration)  
 100 0000: ICP sector of bank 2  
 other configurations: reserved
- Bit 7 **START2**: Bank 2 bank or sector erase start control bit  
 START2 bit is used to start a sector erase or a bank erase operation. START2 can be programmed only when LOCK2 is set to '0'.  
 The Flash memory interface resets START2 when the corresponding operation has been acknowledged. The user application cannot access any Flash register until the operation has been acknowledged.

**Bit 6 FW2:** Bank 2 write forcing control bit

FW2 forces a write operation even if the write buffer is not full. FW2 can be programmed only when LOCK2 is set to '0'.

The Flash memory interface resets FW2 when the corresponding operation has been acknowledged, The user application cannot access any Flash register until the operation has been acknowledged.

Write forcing is effective only if the write buffer is not empty (in particular, FW2 will not start several write operations when the write operations are performed consecutively).

**Bits 5:4 PSIZE2:** Bank 2 program size

PSIZE2 selects the parallelism used by the Flash memory during write and erase operations to bank 2(refer to [Section : Configuring the programming parameters](#) for details). PSIZE2 can be programmed only when LOCK2 is set to '0'.

00: programming executed with byte parallelism

01: programming executed with half-word parallelism

10: programming executed with word parallelism

11: programming executed with double word parallelism.

**Bit 3 BER2:** Bank 2 erase request

Setting BER2 bit to '1' requests a bank erase operation on bank 2. BER2 can be programmed only when LOCK2 is set to '0'.

BER2 has a higher priority than SER2: if both are set, the Flash memory interface executes a bank erase (for more details, see [Section : Standard Flash bank erase](#)).

0: bank erase not requested on bank 2

1: bank erase requested on bank 2.

**Bit 2 SER2:** Bank 2 sector erase request

Setting SER2 bit to '1' requests a sector erase on bank 2. SER2 can be programmed only when LOCK2 is set to '0'.

BER2 has a higher priority than SER2: if both are set, the Flash memory interface executes a bank erase (for more details, see [Section : Flash sector erase](#)).

0: sector erase not requested on bank 2

1: sector erase requested on bank 2.

**Bit 1 PG2:** Bank 2 program enable bit

Setting PG2 bit to '1' enables write operations to bank 2. This allows preparing program operations even if a sector or bank erase is ongoing.

PG2 can be programmed only when LOCK2 is set to '0'. When PG2 is reset, the internal buffer is disabled for write operations to bank 2, and all the data stored in the buffer but not yet programmed are lost.

**Bit 0 LOCK2:** Bank 2 configuration lock bit

This bit locks the FLASH\_CR2 register.

When the FLASH\_CR2 register is unlocked, LOCK2 bit is automatically reset (see [Section : Configuring the programming parameters](#)). If a wrong sequence is executed, this bit remains locked until next system reset.

LOCK2 can be set by programming it to '1'. When set to '1', a new unlock sequence is mandatory to unlock it. When LOCK2 changes from '0' to '1', the other bits of FLASH\_CR2 register do not change.

### 3.5.26 FLASH status register for bank 2 (FLASH\_SR2)

Address offset: 0x110

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CRCEND2	DBECCERR2	SNECCERR2	RDSERR2	RDPERR2	OPERR2	INCERR2	Res.	STRBERR2	PGSERR2	WRPERR2	EOF2
				r	r	r	r	r	r	r		r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_BUSY2	QW2	WBNE2	BSY2
												r	r	r	r

Bits 31:28 Reserved, must be kept at reset value

Bit 27 **CRCEND2**: Bank 2 CRC-complete flag

CRCEND2 bit is raised when the CRC computation has completed on bank 2. An interrupt is generated if CRCENDIE2 is set to '1'. It is not necessary to reset CRCEND2 before restarting CRC computation. Writing '1' to CLR\_CRCEND2 bit in FLASH\_CCR2 register clears CRCEND2.

- 0: CRC computation not complete on bank 2
- 1: CRC computation complete on bank 2

Bit 26 **DBECCERR2**: Bank 2 ECC double detection error flag

DBECCERR2 flag is raised when an ECC double detection error occurs during a read operation from bank 2. An interrupt is generated if DBECCERRIE2 is set to '1'. Writing '1' to CLR\_DBECCERR2 bit in FLASH\_CCR2 register clears DBECCERR2.

- 0: no ECC double detection error occurs on bank 2
- 1: ECC double detection error occurs on bank 2

Bit 25 **SNECCERR2**: Bank 2 single correction error flag

SNECCERR2 flag is raised when an ECC single correction error occurs during a read operation from bank 2. An interrupt is generated if SNECCERRIE2 is set to '1'. Writing '1' to CLR\_SNECCERR2 bit in FLASH\_CCR2 register clears SNECCERR2.

- 0: no ECC single correction error occurs on bank 2
- 1: ECC single correction error occurs on bank 2

Bit 24 **RDSERR2**: Bank 2 secure error flag

RDSERR2 flag is raised when an secure error (access to a secure protected word without the appropriate rights) occurs on bank 2. An interrupt is generated if RDSERRIE2 is set to '1'. Writing '1' to CLR\_RDSERR2 bit in FLASH\_CCR2 register clears RDSERR2.

- 0: no secure error occurs on bank 2
- 1: a secure error occurs on bank 2

- Bit 23 **RDPERR2**: Bank 2 read protection error flag  
RDPERR2 flag is raised when an read protection error (access to a PCROP-protected word) occurs on bank 2. An interrupt is generated if RDPERRIE2 is set to '1'. Writing '1' to CLR\_RDPERR2 bit in FLASH\_CCR2 register clears RDPERR2.  
0: no read protection error occurs on bank 2  
1: a read protection error occurs on bank 2
- Bit 22 **OPERR2**: Bank 2 write/erase error flag  
OPERR2 flag is raised when an error occurs during a write/erase to/from bank 2. An interrupt is generated if OPERRIE2 is 1 set to '1'. Writing '1' to CLR\_OPERR2 bit in FLASH\_CCR2 register clears OPERR2.  
0: no write/erase error occurs on bank 2  
1: a write/erase error occurs on bank 2
- Bit 21 **INCERR2**: Bank 2 inconsistency error flag  
INCERR2 flag is raised when a inconsistency error occurs on bank 2. An interrupt is generated if INCERRIE2 is set to '1'. Writing '1' to CLR\_INCERR2 bit in the FLASH\_CCR2 register clears INCERR2.  
0: no inconsistency error occurs on bank 2  
1: a inconsistency error occurs on bank 2.
- Bit 20 Reserved, must be kept at reset value
- Bit 19 **STRBERR2**: Bank 2 strobe error flag  
STRBERR2 flag is raised when a strobe error occurs on bank 2 (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE2 bit is set to '1'. Writing '1' to CLR\_STRBERR2 bit in FLASH\_CCR2 register clears STRBERR2.  
0: no strobe error occurs on bank 2  
1: a strobe error occurs on bank 2.
- Bit 18 **PGSERR2**: Bank 2 programming sequence error flag  
PGSERR2 flag is raised when a sequence error occurs on bank 2. An interrupt is generated if the PGSERRIE2 bit is set to '1'. Writing '1' to CLR\_PGSERR2 bit in FLASH\_CCR2 register clears PGSERR2.  
0: no sequence error occurs on bank 2  
1: a sequence error occurs on bank 2.
- Bit 17 **WRPERR2**: Bank 2 write protection error flag  
WRPERR2 flag is raised when a protection error occurs during a program operation to bank 2. An interrupt is also generated if the EOPIE2 is set to '1'. Writing '1' to CLR\_EOP2 bit in FLASH\_CCR2 register clears WRPERR2.  
0: no protection error occurs on bank 2  
1: a protection error occurs on bank 2
- Bit 16 **EOP2**: Bank 2 end-of-program flag  
EOP2 flag is set when a programming operation to bank 2 completes. An interrupt is generated if the EOPIE2 is set to '1'. It is not necessary to reset EOP2 before starting a new operation. EOP2 bit is cleared by writing '1' to CLR\_EOP2 bit in FLASH\_CCR2 register.  
0: no programming operation completed on bank 2  
1: a programming operation completed on bank 2
- Bits 15:4 Reserved, must be kept at reset value

**Bit 3 CRC\_BUSY2:** Bank 2CRC busy flag

CRC\_BUSY2 flag is set when a CRC calculation is ongoing on bank 2. This bit cannot be forced to '0'. The user must wait until the CRC calculation has completed or disable CRC computation on bank 2.

0: no CRC calculation ongoing on bank 2

1: CRC calculation ongoing on bank 2.

**Bit 2 QW2:** Bank 2 wait queue flag

QW2 flag is set when a program operation to bank 2 is in the waiting queue. It is not possible to know what type of programming operation is in the queue. When all program operations have been executed and thus removed from the waiting queue, this flag is reset by hardware. This bit cannot be forced to '0'. It is reset after a deterministic time if no other operations are requested.

0: no program operations waiting in the operation queue of bank 2

1: at least one programming operation is waiting in the operation queue of bank 2

**Bit 1 WBNE2:** Bank 2 write buffer not empty flag

WBNE2 flag is set when bank 2 write buffer is not empty and the Flash memory interface is waiting for new data to complete it.

WBNE2 is reset by hardware each time the write buffer is emptied. This happens when one of the following event occurs:

- the write buffer is full
- the user forces the write operation
- an error that involves data loss occurs
- the write operation has been disabled.

This bit cannot be forced to '0'. To reset it, clear the write buffer by performing any of the above listed actions.

0: write buffer of bank 2 empty

1: write buffer of bank 2 waiting data to complete.

**Bit 0 BSY2:** Bank 2 ongoing program flag

BSY2 flag is set when a program operation to bank 1 is ongoing. It is not possible to know what type of program operation is ongoing.

BSY2 cannot be forced to '0'. It is reset by hardware when the operation completes, provided no other program operation starts.

0: no programming operation executing on bank 2

1: programming operation executing on bank 2.

### 3.5.27 FLASH clear control register for bank 2 (FLASH\_CCR2)

Address offset: 0x114

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value

Bit 27 **CLR\_CRCEND2**: Bank 2 CRCEND2 flag clear bit

Setting this bit to '1' resets to '0' CRCEND2 flag of FLASH\_SR2 register.

Bit 26 **CLR\_DBECERR2**: Bank 2 DBECERR2 flag clear bit

Setting this bit to '1' resets to '0' DBECERR2 flag of FLASH\_SR2 register. If the SNECCERR2 flag of FLASH\_SR2 register is set to '0', FLASH\_ECC\_FA2R register are reset to '0' as well.

Bit 25 **CLR\_SNECCERR2**: Bank 2 SNECCERR2 flag clear bit

Setting this bit to '1' resets to '0' SNECCERR2 flag of FLASH\_SR2 register. If the DBECERR2 flag of FLASH\_SR2 register is set to '0', FLASH\_ECC\_FA2R register are reset to '0' as well.

Bit 24 **CLR\_RDSERR2**: Bank 2 RDSERR2 flag clear bit

Setting this bit to '1' resets to '0' RDSERR2 flag of FLASH\_SR2 register.

Bit 23 **CLR\_RDPERR2**: Bank 2 RDPERR2 flag clear bit

Setting this bit to 1 resets to '0' RDPERR2 flag of FLASH\_SR2 register.

Bit 22 **CLR\_OPERR2**: Bank 2 OPERR2 flag clear bit

Setting this bit to '1' resets to '0' **OPERR2** flag of FLASH\_SR2 register.

Bit 21 **CLR\_INCERR2**: Bank 2 INCERR2 flag clear bit

Setting this bit to '1' resets to '0' INCERR2 flag of FLASH\_SR2 register.

Bit 20 Reserved, must be kept at reset value

Bit 19 **CLR\_STRBERR2**: Bank 2 STRBERR2 flag clear bit

Setting this bit to '1' resets to '0' STRBERR2 flag of FLASH\_SR2 register.

Bit 18 **CLR\_PGSERR2**: Bank 2 PGSERR2 flag clear bit

Setting this bit to '1' resets to '0' PGSERR2 flag of FLASH\_SR2 register.

Bit 17 **CLR\_WRPERR2**: Bank 2 WRPERR2 flag clear bit  
 Setting this bit to '1' resets to '0' WRPERR2 flag of FLASH\_SR2 register.

Bit 16 **CLR\_EOP2**: Bank 2 EOP2 flag clear bit  
 Setting this bit to '1' resets to '0' EOP2 flag of FLASH\_SR2 register.

Bits 15:0 Reserved, must be kept at reset value

### 3.5.28 FLASH protection address for bank 2 (current value) (FLASH\_PRAR\_CUR2)

Address offset: 0x128

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP2	Res.	Res.	Res.	PROT_AREA_END2											
	r			r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PROT_AREA_START2											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMEP2**: Bank 2 PCROP protected erase enable option status bit  
 If DMEP2 is set to '1', the PCROP protected areas are erased when a protection level regression (change from level 1 to 0) occurs (see [Section : PCROP area \(proprietary code readout protection, execute-only area\)](#) and [Section : Standard Flash bank erase](#)).

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **PROT\_AREA\_END2**: Bank 2 highest PCROP protected address  
 These bits contain the last address protected by PCROP in bank 2.  
 If this address is equal to PROT\_AREA\_START2, the whole bank 2 is PCROP protected.  
 If this address is lower than PROT\_AREA\_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **PROT\_AREA\_START2**: Bank 2 lowest PCROP protected address  
 These bits contain the first address protected by PCROP in bank 2.  
 If this address is equal to PROT\_AREA\_END2, the whole bank 2 is PCROP protected.  
 If this address is higher than PROT\_AREA\_END2, no protection is set on bank 1.

### 3.5.29 FLASH protection address for bank 2 (value to program) (FLASH\_PRAR\_PRG2)

Address offset: 0x12C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMEP2	Res.	Res.	Res.	PROT_AREA_END2											
r/w				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PROT_AREA_START2											
				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bit 31 **DMEP2**: Bank 2 PCROP protected erase enable option configuration bit  
 If DMEP2 is set to '1', the PCROP protected areas are erased when a protection level regression (change from level 1 to 0) or a bank 2 erase occurs (see [Section : PCROP area \(proprietary code readout protection, execute-only area\)](#)).

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **PROT\_AREA\_END2**: Bank 2 highest PCROP protected address configuration  
 These bits allow configuring the last PCROP protected address in bank 2.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **PROT\_AREA\_START2**: Bank 2 lowest PCROP protected address configuration  
 These bits allow configuring the first PCROP protected address in bank 2.

### 3.5.30 FLASH secure address for bank 2 (current value) (FLASH\_SCAR\_CUR2)

Address offset: 0x130

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES2	Res.	Res.	Res.	SEC_AREA_END2											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	SEC_AREA_START2											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **DMES2**: Bank 2 secure protected erase enable option status bit  
 If DMES2 is set to '1', the secure protected areas are erased when a protection level regression (change from level 1 to 0) occurs (see [Section : Secure area](#) and [Section : Standard Flash bank erase](#)).

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **SEC\_AREA\_END2**: Bank 2 highest secure protected address  
 These bits contain the last secure protected address in bank 2.  
 If this address is equal to SEC\_AREA\_START2, the whole bank 2 is secure protected.  
 If this address is lower than SEC\_AREA\_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **SEC\_AREA\_START2**: Bank 2 lowest secure protected address  
 These bits contain the first secure protected address in bank 2.  
 If this address is equal to SEC\_AREA\_END2, the whole bank 2 secure protected.  
 If this address is higher than SEC\_AREA\_END2, no protection is set on bank 2.

### 3.5.31 FLASH secure address for bank 2 (value to program) (FLASH\_SCAR\_PRG2)

Address offset: 0x134

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMES2	Res.	Res.	Res.	SEC_AREA_END2											
r/w				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	SEC_AREA_START2											
				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bit 31 **DMES2**: Bank 2 secure protected erase enable option configuration bit  
 If DMES2 is set to '1', the secure protected areas are erased when a protection level regression (change from level 1 to 0) or a bank 2 erase occurs (see [Section : Secure area](#)),

Bits 30:28 Reserved, must be kept at reset value

Bits 27:16 **SEC\_AREA\_END2**: Bank 2 highest secure protected address configuration  
 These bit allow configuring the last secure protected address in bank 2. This bit can be programmed only in secure mode.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **SEC\_AREA\_START2**: Bank 2lowest secure protected address configuration  
 These bit allow configuring the first secure protected address in bank 2. This bit can be programmed only in secure mode.

### 3.5.32 FLASH write sector protection for bank 2 (current value) (FLASH\_WPSN\_CUR2R)

Address offset: 0x138

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPSn2							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **WRPSn2**: Bank 2 sector write protection status byte

Each FLASH\_WPSN\_CUR2R bit reflects the write protection status of the corresponding bank 2 sector.

### 3.5.33 FLASH write sector protection for bank 2 (value to program) (FLASH\_WPSN\_PRG2R)

Address offset: 0x13C

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPSn2							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **WRPSn2**: Bank 2 sector write protection configuration byte

Setting WRPSn2 bit to '0' allows write protecting the corresponding bank 2 sector.

### 3.5.34 FLASH CRC control register for bank 2 (FLASH\_CRCCR2)

Address offset: 0x150

Reset value: 0x001C 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRC_BURST		Res.	Res.	CLEAN_CRC	START_CRC
										r/w	r/w			w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CLEAN_SECT	ADD_SECT	CRC_BY_SECT	ALL_BANK	Res.	Res.	Res.	Res.	CRC_SECT		
					w	w	r/w	w					r/w	r/w	r/w

Bits 31:22 Reserved, must be kept at reset value

v 21:20 **CRC\_BURST**: Bank 2 CRC burst size

CRC\_BURST bits set the size of the bursts that are generated by the CRC calculation unit.

00: every burst has a size of 4 words

01: every burst has a size of 16 words

10: every burst has a size of 64 words

11: every burst has a size of 256 words

Bits 19:18 Reserved, must be kept at reset value

Bit 17 **CLEAN\_CRC**: Bank 2 CRC clear bit

Setting CLEAN\_CRC to '1' clears the current CRC result stored in the FLASH\_CRCDATAR register.

Bit 16 **START\_CRC**: Bank 2 CRC start bit

START\_CRC bit triggers a CRC calculation on bank 2 using the current configuration. It is not possible to start a CRC calculation when an option byte change operation is ongoing because all write accesses to Flash registers are put on hold until the option byte change operation has completed.

Bits 15:13 Reserved, must be kept at reset value

Bits 12:11 Reserved, must be kept at reset value

Bit 10 **CLEAN\_SECT**: Bank 2 CRC sector list clear bit

Setting CLEAN\_SECT to '1' clears the list of sectors on which the CRC is calculated.

Bit 9 **ADD\_SECT**: Bank 2 CRC sector select bit

Setting ADD\_SECT to '1' adds the sector whose number is CRC\_SECT to the list of sectors on which the CRC is calculated.

Bit 8 **CRC\_BY\_SECT**: Bank 2 CRC sector mode select bit  
 When CRC\_BY\_SECT is set to '1', the CRC calculation is performed at sector level, on the sectors selected by CRC\_SECT.  
 When CRC\_BY\_SECT is reset to '0', the CRC calculation is performed on all addresses between CRC\_START\_ADDR and CRC\_END\_ADDR.

Bit 7 **ALL\_BANK**: Bank 2 CRC select bit  
 When ALL\_BANK is set to '1', all bank 2 user sectors are added to list of sectors on which the CRC is calculated.

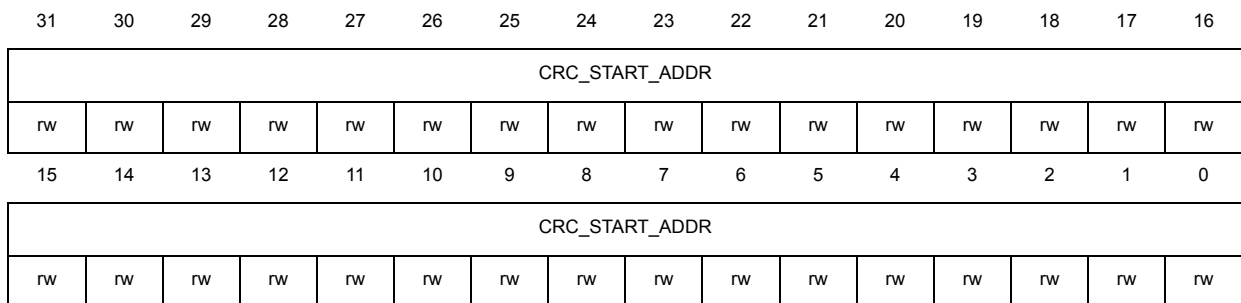

Bits 6:3 Reserved, must be kept at reset value

Bits 2:0 **CRC\_SECT**: Bank 2 CRC sector number  
 CRC\_SECT is used to select one or more sectors to be added to CRC calculation. The CRC can be computed either between two addresses (start address and end address) or on a list of sectors. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC\_SECT and then setting to '1' ADD\_SECT.  
 The list of sectors can be erased either by setting CLEAN\_SECT bit or by disabling the CRC computation. To know the number of each sector, refer to the description of SNB2 bits in FLASH\_CR register (see [Section 3.5.25: FLASH control register for bank 2 \(FLASH\\_CR2\)](#)).  
 CRC\_SECT can be set only when CRC\_EN of FLASH\_CR register is set to '1'.

### 3.5.35 FLASH CRC start address register for bank 2 (FLASH\_CRCSADD2R)

Address offset: 0x154

Reset value: 0x0000 0000

Bits 31:0 **CRC\_START\_ADDR**: CRC start address on bank 2  
 CRC\_START\_ADDR is used when CRC\_BY\_SECT is '0'. It must be programmed to the start address of the bank 2 memory area on which the CRC calculation is performed.

### 3.5.36 FLASH CRC end address register for bank 2 (FLASH\_CRCEADD2R)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_END_ADDR															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_END_ADDR															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:0 **CRC\_END\_ADDR**: CRC end address on bank 2

CRC\_END\_ADDR is used when CRC\_BY\_SECT is '0'. It must be programmed to the end address of the bank 2 memory area on which the CRC calculation is performed.

### 3.5.37 FLASH ECC fail address for bank 2 (FLASH\_ECC\_FA2R)

Address offset: 0x160

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FAIL_ECC_ADDR2														
	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:15 Reserved, must be kept at reset value

Bits 14:0 **FAIL\_ECC\_ADDR2**: Bank 2 ECC error address

When an ECC error occurs (both for single error correction or double detection) during a read operation from bank 2, the FAIL\_ECC\_ADDR2 bitfield contains the address that generated the error.

FAIL\_ECC\_ADDR2 is reset when the flag error in the FLASH\_SR2 register (CLR\_SNECCERR2 or CLR\_DBECCERR2) is reset.

The Flash memory interface programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.

### 3.6 FLASH register map and reset values

Table 16. Register map and reset value table

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 4 Security memory management

### 4.1 Introduction

STM32H7x3 microcontrollers offer a first set of protection mechanisms, which are similar to the latest STM32 Series (STM32F4/F7 and STM32L0/L4):

- Global readout device protection
- Write protection
- Proprietary code readout protection (PCROP)

A summary of these protection mechanisms is given in [Section 4.3: Flash protections](#).

STM32H7x3 also offer a new enhanced protection mode, the Secure access mode, that makes possible the development of user-defined secure services (e.g. secure firmware update) and guarantees of a safe execution and protection of both code and data. This new mechanism is described in details in [Section 4.4: Secure access mode](#), [Section 4.5: Root secure services \(RSS\)](#) and [Section 4.6: Secure user software](#).

The security memory management unit is contained inside the D1 domain.

### 4.2 Glossary

The following terms will be used in herein:

**Table 17. List of preferred terms**

Term	Description
<b>Device Security Level</b>	
Standard mode	Device state which allows accessing the user Flash memory, the option bytes and the bootloader area
Secure access mode	Device state which allows to access all the memory areas of the device
<b>Memory areas</b>	
System memory	ST reserved memory area used to store ST ROM code
User Flash memory	Flash memory area used to store user code and data
Secure user memory/area	This area can be configured to be accessed once after reset and be hidden for the firmware stored in the user Flash memory after the code stored in this area is executed.

**Table 17. List of preferred terms (continued)**

Term	Description
<b>SW services</b>	
Bootloader	STMicroelectronics software executed at reset which allows downloading firmware from regular communication port
Root secure services (RSS)	STMicroelectronics software which allows encrypted firmware/module decryption and installation into secure and non-secure user memory
Secure bootloader	Complementary services composed by an STMicroelectronics bootloader plus ST root secure services.
Secure user software	User software executed once after reset, which can be used to store SFU and firmware initialization. Secure User SW is located in Secure User Memory
Secure Firmware Update (SFU)	User software used to download and update installed firmware from user Flash memory

### 4.3 Flash protections

Three protection mechanisms can be used in the end-user application or during development involving proprietary code (such as third-party libraries):

- Readout device protection (RDP)  
This is a global protection mechanism, which is suitable for end products. It prevents the device from being accessed externally through the debug port or boot from RAM or bootloader.
- Proprietary code readout protection (PCROP)  
This mechanism can be set on specific Flash memory areas that must be execute-only. PCROP is used to avoid sensitive software dumping.
- Write protection  
This protection can be set at Flash sector level. It prevents code or data from being accidentally erased.

*Table 18* summarizes the protection mechanisms that are available on STM32H7x3 as well as most STM32 devices. On STM32H7x3, they are available both in Standard and Secure access modes.

For further details, refer to [Section 3: Embedded Flash memory \(FLASH\)](#).

Table 18. Flash protection mechanisms

Flash Protection	Scope	Description
RDP	Global (All sectors of all banks + backup SRAM)	Protection Level 1: – No access (read, erase and program) to Flash memory or backup SRAM can be performed when the debugger is connected or when the boot configuration is different from user Flash memory. – Protection can be removed by performing Flash mass erase Protection level 2: – Debug access (SW or JTAG) disabled – No System bootloader access <sup>(1)</sup> – No RAM boot allowed – Protection level2 is permanent
Write protection	At sector level (128 Kbytes)	Protection against unwanted write/modification of user Flash memory sectors
PCROP/execute-only area	At area level (256-byte granularity)	Only execute accesses are allowed. This protection is set on sensitive code to prevent debug accesses and code copy by other software.

1. Access to root secure services in Secure access mode is allowed. Refer to [Section 4.4: Secure access mode](#).

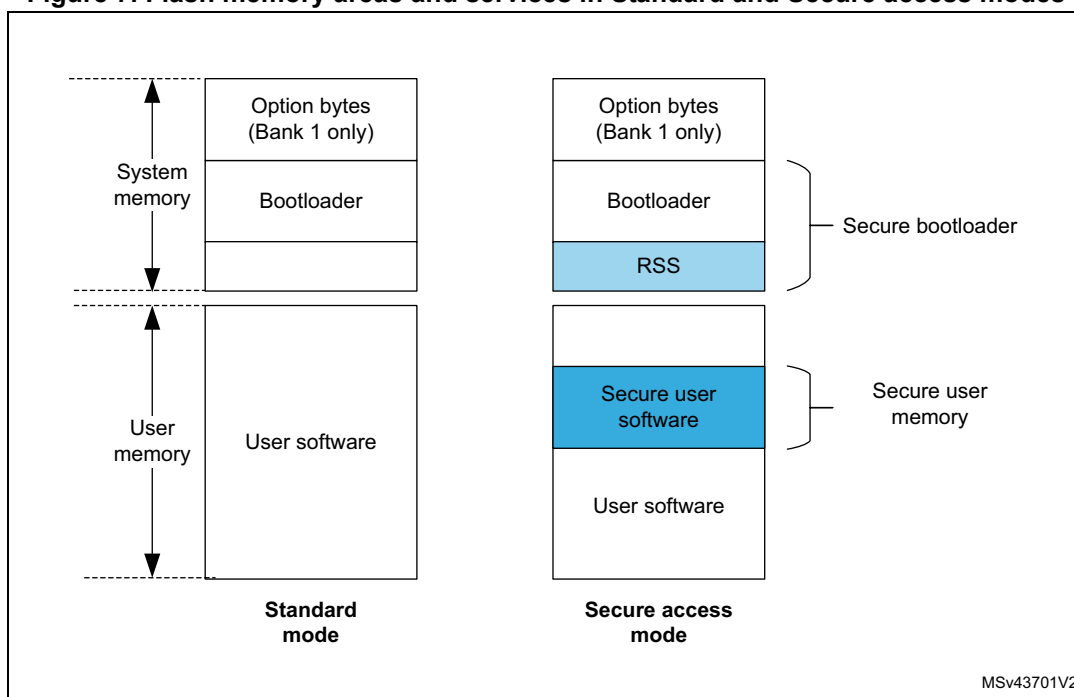

## 4.4 Secure access mode

Some sensitive functions require safe execution from potential malicious software attacks. Secure firmware update (SFU) software is a good example of code that requires a high level of protection since it handles secret data (such as encrypted firmware or cryptographic keys) that shall not be retrieved by other processes.

STM32H7x3 microcontrollers feature secure memory areas with restricted access. They allow building secure services that will be executed prior to any user application. These secure areas, together with the software they contain, are only accessible when configuring a new device in Secure access mode.

[Figure 7](#) gives an overview of Flash memory areas and services in Standard and Secure access modes.

Figure 7. Flash memory areas and services in Standard and Secure access modes

1. The protected areas that can only be accessed in Secure access mode are shown in blue.

#### 4.4.1 Associated features

The Secure access mode can be configured through option bytes. When it is set, it enables access to:

- the secure bootloader, which embeds the bootloader plus some secure services provided by STMicroelectronics (see [Section 4.5: Root secure services \(RSS\)](#))
- Secure user memory which embeds secure user code and data.

For a summary of access rights for each core, refer to [Section 4.7: Summary of Flash protection mechanisms](#).

#### 4.4.2 Boot state machine

In Secure access mode, the secure bootloader replaces the standard bootloader. Booting in the RSS is forced independently from boot configuration (boot pins and boot addresses). Root secure services and Secure user software will hence preempt all other codes in the device (including classical bootloader).

##### Execution priority

1. Root secure services have the highest priority after a system reset. The service called will be executed and a new system reset will be triggered immediately afterwards. The available secure services are detailed in [Section 4.5: Root secure services \(RSS\)](#).
2. If no service is requested, the Secure user software will be executed provided it has been defined and the boot address has been set accordingly. Refer to [Section 4.6: Secure user software](#) for Secure user software settings.
3. Otherwise, the classical boot state-machine will be followed: bootloader or boot from Flash memory.

Figure 8 shows STM32H7x3 boot state machine.

Figure 8. Secure bootloader state machine

### 4.4.3 Secure access mode configuration

#### Enabling Secure access mode

There is no restriction on how to activate Secure access mode on the device. It is configured through the SECURITY option bit in FLASH\_OPTSR\_CUR register (see [Section 3.5.8: FLASH option status register \(current value\) \(FLASH\\_OPTSR\\_CUR\)](#)).

The Secure access mode becomes active after a system reset.

#### Disabling Secure access mode

Disabling Secure access mode is a more sensitive task as it can only be done if no more protected code exists on the device. As a result, to come back to Standard mode, Secure user memories and PCROP/execute-only areas shall be removed before clearing the SECURITY option bit in the FLASH\_OPTSR\_CUR register.

Protected areas can be removed either by performing a Flash mass erase, a bank erase or by calling a dedicated secure service (for PCROP areas only):

- Refer to [Section : PCROP area \(proprietary code readout protection, execute-only area\)](#) and to [RSS\\_resetAndDestroyPCROPArea](#) secure service for removing PCROP protection.
- Refer to [Section 3.3.12: Protection mechanisms](#) for an explanation on how to remove secure areas.

## 4.5 Root secure services (RSS)

STMicroelectronics provides services to configure secure areas. These root secure services are executed after a system reset in Secure access mode and prior to any other software stored in the device.

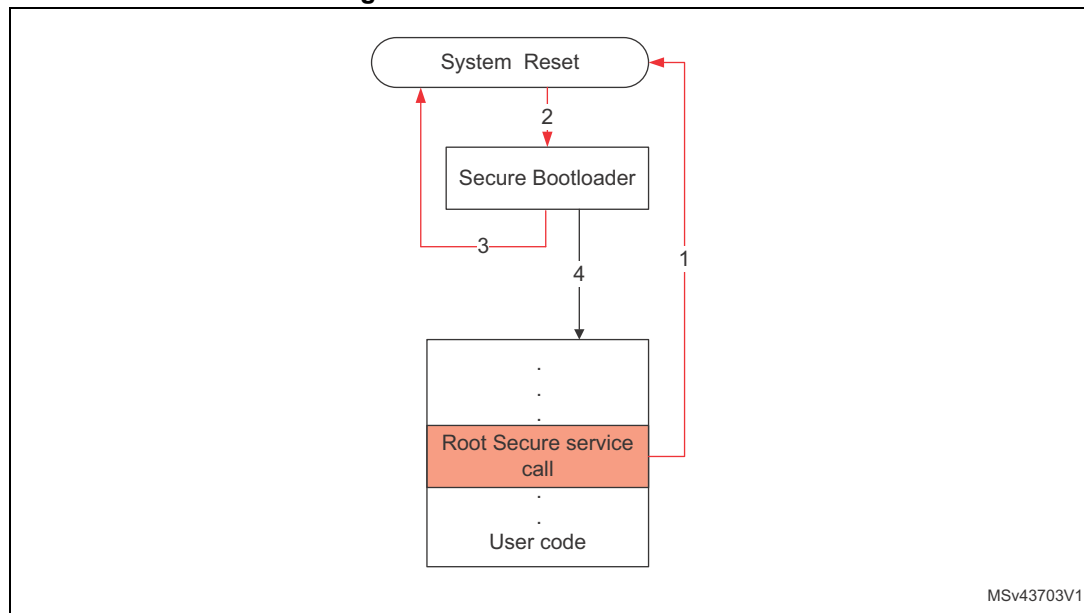

RSS software cannot be accessed (read, write, execute and debug) when the STM32H7x3 operates in Standard mode.

When the STM32H7x3 is configured in Secure access mode, the RSS software is executed only once at reset. When RSS software execution is complete, it cannot be accessed anymore (no other code can jump directly to RSS). Any RSS routine is called by performing a reset.

### 4.5.1 Calling root secure services

A secure service is called through a public API that triggers a software reset (see [Figure 9](#), step 1) so that the secure bootloader is executed with RSS code available (see [Figure 9](#), step 2). Once executed, most services trigger a system reset (see [Figure 9](#), step 3) and as no more service is required, the secure bootloader jumps to the user software (see [Figure 9](#), step 4).

Figure 9. Root secure service call

MSv43703V1

## 4.5.2 Root secure services description

The following secure services are available for managing PCROP, secure user memory and secure mode settings.

### RSS\_resetAndInitializeSecureAreas

<b>Prototype</b>	void RSS_resetAndInitializeSecureAreas(RSS_SecureArea_t area)
<b>Arguments</b>	Secure user areas start and end addresses. One or two Secure user areas can be set.
<b>Description</b>	<p>This service sets Secure user area boundaries, following the values stored in the option byte registers:</p> <ul style="list-style-type: none"> <li>– SEC_AREA_START1 and SEC_AREA_END1 for bank 1</li> <li>– SEC_AREA_START2 and SEC_AREA_END2 for bank 12</li> </ul> <p>This service can be used only when a secure area is set for the first time. A system reset is triggered after service completion.</p>

### RSS\_exitSecureArea

<b>Prototype</b>	void RSS_exitSecureArea(unsigned int vectors)
<b>Arguments</b>	Address of application vectors where to jump after exit
<b>Description</b>	<p>This service is used to exit from secure user software and jump to user main application.</p> <p>There is no system reset triggered by this service</p>

### RSS\_resetAndDestroyPCROPArea

<b>Prototype</b>	RSS_resetAndDestroyPCROPArea(RSS_FlashBank_et bank)
<b>Arguments</b>	Targeted bank number
<b>Description</b>	<p>This service overwrites PCROP area and removes the PCROP protection.</p> <p>Avoid a Flash/bank mass erase.</p> <p>A system reset is triggered after service completion</p>

## 4.6 Secure user software

A Secure user software is a trusted piece of code that is executed after device power-on or after a system reset. It allows building secure applications such as:

- code signature or integrity checking (user secure boot).
- software license checking
- secure firmware update

### 4.6.1 Access rules

Only accessible in Secure access mode, the Secure user software is stored in the secure user memory, a configurable protected area which is part of the user main memory.

Only one user secure area per bank can be configured.

Only root secure services have higher priority and can preempt secure user software execution (see [Section 4.4.2: Boot state machine](#)).

After secure user software execution, the code shall jump to the main user application and prevent access to the secure user area. This is done by calling `RSS_exitSecureAreas` secure service with the application code address given as parameter.

Once in the application code, any access to the secure user area triggers a Flash error.

### 4.6.2 Setting secure user memory areas

One secure area of configurable size can be set in each bank. The size of each area can be set from 512 bytes to full bank with a granularity of 256 bytes:

- Secure area in bank 1  
Boundaries are configured through SEC\_AREA\_START1 and SEC\_AREA\_END1 option bits in FLASH\_SCAR\_CUR1 (see [Section 3.5.13: FLASH secure address for bank 1 \(current value\) \(FLASH\\_SCAR\\_CUR1\)](#)).
- Secure area in bank 2  
Boundaries are configured through SEC\_AREA\_START2 and SEC\_AREA\_END2 option bits in FLASH\_SCAR\_CUR2 (see [Section 3.5.30: FLASH secure address for bank 2 \(current value\) \(FLASH\\_SCAR\\_CUR2\)](#)).

*Note:* If the secure area start address is equal to the secure area end address, the full bank is considered as secure protected.

Active setting then differs depending on whether a secure user area is defined or not in the device:

- No secure user area exists (first time setting):  
A dedicated root secure service, `RSS_resetAndInitializeSecureAreas`, shall be called to initialize the empty address in the ST boot state machine. Both secure areas (one per bank) can be set in the same operation.
- A secure user area already exists:  
In this case, the secure user area code can update its own secure user area size or create a new one in the other bank.  
Note that `RSS_resetAndInitializeSecureAreas` function cannot be used to create a second user secure area.

### 4.6.3 Removing secure user memory areas

Secure user areas can only be erased by performing a Flash mass erase or a bank erase operation.

- A Flash mass erase is triggered by a level regression from RDP level 1 to RDP level 0.
- A bank erase is triggered by setting BER1/2 bit of FLASH\_CR1/2 register (see [Section 3.5.4: FLASH control register for bank 1 \(FLASH\\_CR1\)](#) and [Section 3.5.25: FLASH control register for bank 2 \(FLASH\\_CR2\)](#)).

In both cases, the DMES1/2 bit that defines the erase policy in the FLASH\_PRAR\_CUR1/2 register (see [Section 3.5.11: FLASH protection address for bank 1 \(current value\) \(FLASH\\_PRAR\\_CUR1\)](#) and [Section 3.5.28: FLASH protection address for bank 2 \(current value\) \(FLASH\\_PRAR\\_CUR2\)](#)) shall be set to 1 and the area start address shall be superior to its end address.

#### 4.6.4 Selecting secure user software

The current boot address selects one of the two secure user software (one per bank). As two boot addresses can be defined, several use-cases have to be considered.

The selection of the boot address between BOOT\_ADD0 and BOOT\_ADD1 in FLASH\_BOOT\_CURR register is done by the BOOT pin (see [Section 2.5: Boot configuration](#)) or by the swap bank mechanism (see [Section 3.3.13: Flash bank swapping](#)).

[Table 19](#) shows different boot address register setting and the potential associated scenarios.

**Table 19. Secure user software selection use-cases<sup>(1)</sup>**

BOOT_ADD0 (boot pin=0)	BOOT_ADD1 (boot pin=1)	Use case
SEC_AREA_START1	SEC_AREA_START2	Use the BOOT pin to switch between two secure user software (current and recovery or current and previous)
SEC_AREA_START1	SEC_AREA_START1	Use the bank swapping feature to switch between two secure user software starting at same offset in each bank (previous secure boot to current)
SEC_AREA_START1	Recovery firmware	Use the BOOT pin to switch between secure user software and non-secure recovery boot
SEC_AREA_START1	Bootloader	Use BOOT pin for bootloader based recovery (in non-secure mode)

1. Bank number and boot address register number are not related. BOOT\_ADDx or can be set either to bank 1 or to bank 2.

If the boot address is different from the two secure user areas, the system jump directly to the selected address, bypassing the secure user software.

### 4.7 Summary of Flash protection mechanisms

Figure 10 and Table 20 summarize the access rights of the different Flash memory areas, both in Secure access and Standard modes.

Figure 10. Core access to Flash memory areas

Table 20. Flash protected areas access rights summary

Access type	SW Area	Security Mode	Access
Execution	PCROP	Any	?
	Secure user software	Secure access	? <sup>(1)</sup>
	Root secure services	Secure access	? <sup>(1)</sup>
Read access	PCROP	Any	No
	Secure User software	Secure access	√ <sup>(1)</sup>
	Root secure services	Secure access	√ <sup>(1)</sup>
Debug access	PCROP	Any	No
	Secure User software	Secure access	No
	Root secure services	Secure access	No

1. Access rights granted after reset until code completion only.

## 5 AXI interconnect

### 5.1 AXI introduction

The AXI (advanced extensible interface) interconnect is based on the ARM® CoreLink™ NIC-400 Network Interconnect. The interconnect has six initiator ports, or ASIBs (AMBA slave interface blocks), and seven target ports, or AMIBs (AMBA master interface blocks). The ASIBs are connected to the AMIBs via an AXI switch matrix.

Each ASIB is a slave on an AXI bus or AHB (advanced high-performance bus). Similarly, each AMIB is a master on an AXI or AHB bus. Where an ASIB or AMIB is connected to an AHB, it converts between the AHB and the AXI protocol.

The AXI interconnect includes a GPV (global programmer view) which contains registers for configuring certain parameters, such as the QoS (quality of service) level at each ASIB.

Any accesses to unallocated address space are handled by the default slave, which generates the return signals. This ensures that such transactions complete and do not block the issuing master and ASIB.

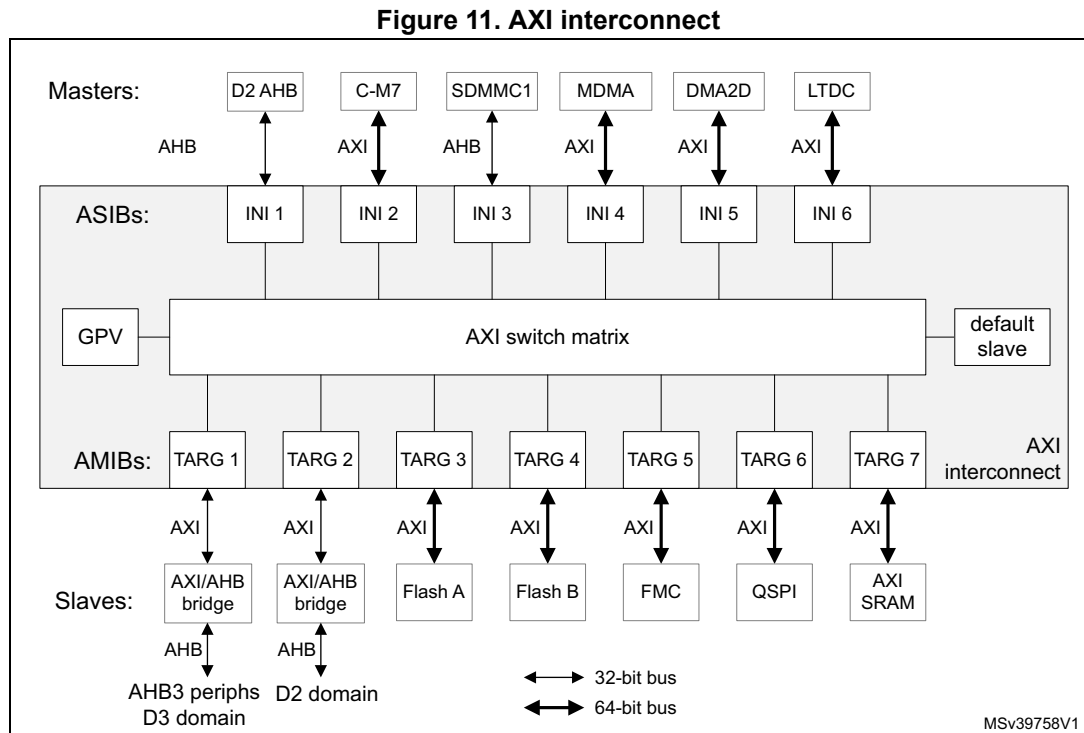

### 5.2 AXI interconnect main features

- 64-bit AXI bus switch matrix with six ASIBs and seven AMIBs, in D1 domain
- AHB/AXI bridge function built into the ASIBs
- concurrent connectivity of multiple ASIBs to multiple AMIBs
- programmable traffic priority management (QoS - quality of service)
- software-configurable via GPV

### 5.3 AXI interconnect functional description

#### 5.3.1 Block diagram

The AXI interconnect is shown in [Figure 11](#).

#### 5.3.2 ASIB configuration

[Table 21](#) summarizes the characteristics of the ASIBs.

**Table 21. ASIB configuration**

ASIB	Connected master	Protocol	Bus width	R/W issuing
INI 1	AHB from D2 domain	AHB-lite	32	1/4
INI 2	Cortex-M7	AXI4	64	7/32
INI 3	SDMMC1	AHB-lite	32	1/4
INI 4	MDMA	AXI4	64	4/1
INI 5	DMA2D	AXI4	64	2/1
INI 6	LTDC	AXI4	64	1/1

### 5.3.3 AMIB configuration

[Table 22](#) summarizes the characteristics of the AMIBs.

**Table 22. AMIB configuration**

AMIB	Connected slave	Protocol	Bus width	R/W/Total acceptance
TARG 1	Peripheral 3 and D3 AHB	AXI4 <sup>(1)</sup>	32	1/1/1
TARG 2	D2 AHB	AXI4 <sup>(1)</sup>	32	1/1/1
TARG 3	Flash A	AXI4	64	3/2/5
TARG 4	Flash B	AXI4	64	3/2/5
TARG 5	FMC	AXI4	64	3/3/6
TARG 6	QUADSPI	AXI4	64	2/1/3
TARG 7	AXI SRAM	AXI3	64	2/2/2

1. Conversion to AHB protocol is done via an AXI/AHB bridge sitting between AXI interconnect and the connected slave.

### 5.3.4 Quality of service (QoS)

The AXI switch matrix uses a priority-based arbitration when two ASIB simultaneously attempt to access the same AMIB. Each ASIB has programmable read channel and write channel priorities, known as QoS, from 0 to 15, such that the higher the value, the higher the priority. The read channel QoS value is programmed in the [AXI interconnect - INI x read QoS register \(AXI\\_INIx\\_READ\\_QOS\)](#), and the write channel in the [AXI interconnect - INI x write QoS register \(AXI\\_INIx\\_WRITE\\_QOS\)](#). The default QoS value for all channels is 0 (lowest priority).

If two coincident transactions arrive at the same AMIB, the higher priority transaction passes before the lower priority. If the two transactions have the same QoS value, then a least-recently-used (LRU) priority scheme is adopted.

The QoS values should be programmed according to the latency requirements for the application. Setting a higher priority for an ASIB ensures a lower latency for transactions initiated by the associated bus master. This can be useful for real-time-constrained tasks, such as graphics processing (LTDC, DMA2D). Assigning a high priority to masters that can make many and frequent accesses to the same slave (such as the Cortex-M7 CPU) can block access to that slave by other lower-priority masters.

### 5.3.5 Global programmer's view (GPV)

The GPV contains configuration registers for the AXI interconnect (see [Section 5.4](#)). These registers are only accessible by the Cortex-M7 CPU.

## 5.4 AXI interconnect registers

### 5.4.1 AXI interconnect - peripheral ID4 register (AXI\_PERIPH\_ID\_4)

Address offset: 0x1FD0

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PARTNUM[7:0]							
								r							

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **PARTNUM[7:0]**: Peripheral part number bits 0 to 7  
 0x00: Part number = 0x400

### 5.4.3 AXI interconnect - peripheral ID1 register (AXI\_PERIPH\_ID\_1)

Address offset: 0x1FE4

Reset value: 0x0000 00B4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JEP106ID[3:0]			PARTNUM[11:8]				
								r			r				

Bits 31:8 Reserved, must be kept at reset value

Bits 7:4 **JEP106ID[3:0]**: JEP106 identity bits 0 to 3  
 0xB: ARM® JEDEC code

Bits 3:0 **PARTNUM[11:8]**: Peripheral part number bits 8 to 11  
 0x4: Part number = 0x400

### 5.4.4 AXI interconnect - peripheral ID2 register (AXI\_PERIPH\_ID\_2)

Address offset: 0x1FE8

Reset value: 0x0000 002B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLASS[3:0]				PREAMBLE[11:8]			
								r				r			

Bits 31:8 Reserved, must be kept at reset value

Bits 7:4 **CLASS[3:0]**: Component class  
 0xF: Generic IP component class

Bits 3:0 **PREAMBLE[11:8]**: Preamble bits 8 to 11  
 0x0: Common ID value

### 5.4.8 AXI interconnect - component ID2 register (AXI\_COMP\_ID\_2)

Address offset: 0x1FF8

Reset value: 0x0000 0005

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PREAMBLE[19:12]							
								r							

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **PREAMBLE[19:12]**: Preamble bits 12 to 19  
 0x05: Common ID value

**5.4.9 AXI interconnect - component ID3 register (AXI\_COMP\_ID\_3)**

Address offset: 0x1FFC

Reset value: 0x0000 00B1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PREAMBLE[27:20]							
								r							

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **PREAMBLE[27:20]**: Preamble bits 20 to 27  
 0xB1: Common ID value

**5.4.10 AXI interconnect - TARG x bus matrix issuing functionality register (AXI\_TARGx\_FN\_MOD\_ISS\_BM)**

Address offset: 0x1008 + 0x1000 \* x, where x = 1 to 7

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRITE_ISS_OVERRIDE	READ_ISS_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value

- Bit 1 **WRITE\_ISS\_OVERRIDE**: Switch matrix write issuing override for target
  - 0: Normal issuing capability
  - 1: Set switch matrix write issuing capability to 1
- Bit 0 **READ\_ISS\_OVERRIDE**: Switch matrix read issuing override for target
  - 0: Normal issuing capability
  - 1: Set switch matrix read issuing capability to 1

**5.4.11 AXI interconnect - TARG x bus matrix functionality 2 register (AXI\_TARGx\_FN\_MOD2)**

Address offset: 0x1024 + 0x1000 \* x, where x = 1, 2 and 7

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS_MERGE
															rw

Bits 31:1 Reserved, must be kept at reset value

Bit 0 **BYPASS\_MERGE**: Disable packing of beats to match the output data width. Unaligned transactions are not realigned to the input data word boundary.

- 0: Normal operation
- 1: Disable packing

**5.4.12 AXI interconnect - TARG x long burst functionality modification register (AXI\_TARGx\_FN\_MOD\_LB)**

Address offset: 0x102C + 0x1000 \* x, where x = 1 and 2

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 6 Power control (PWR)

### 6.1 Introduction

The Power control section (PWR) provides an overview of the supply architecture for the different power domains and of the supply configuration controller.

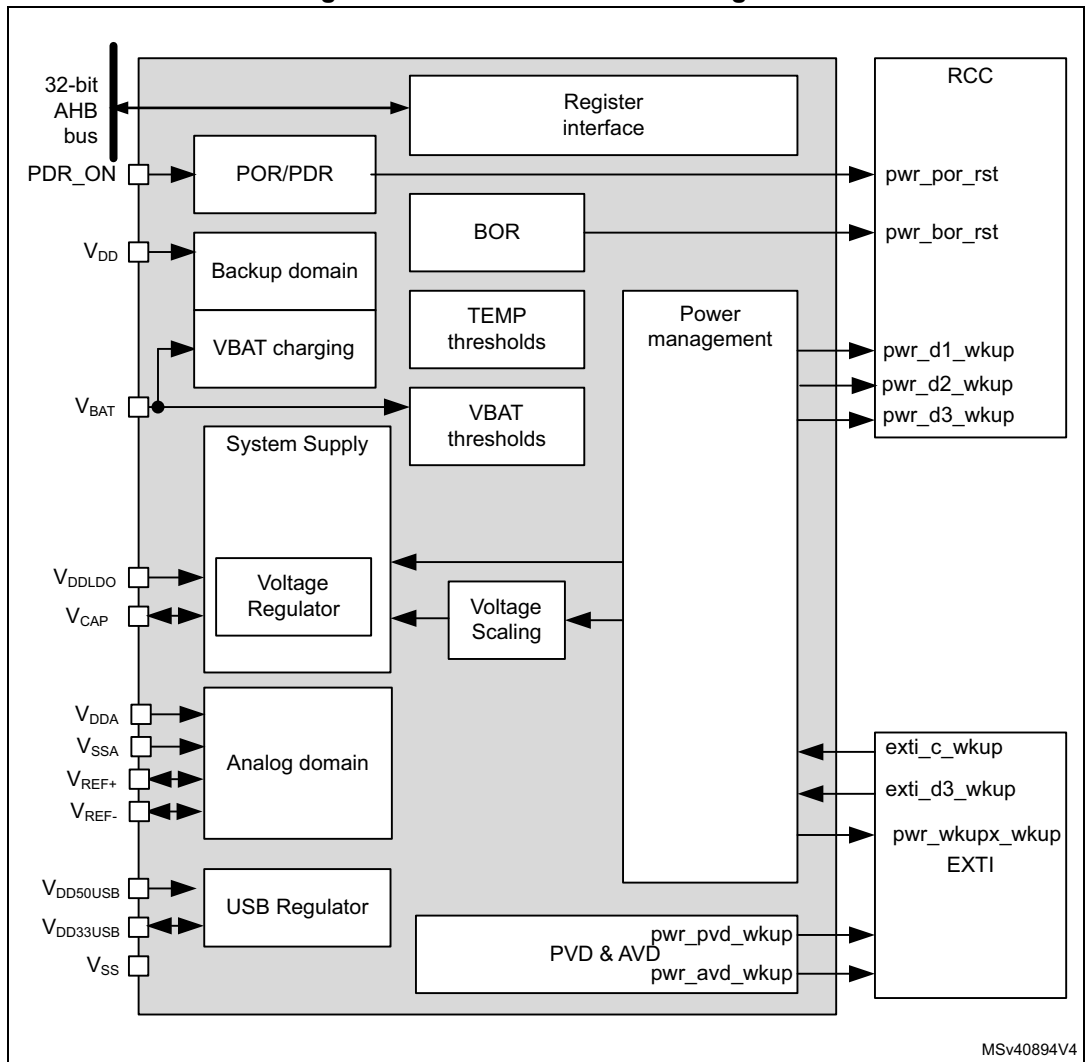

It also describes the features of the power supply supervisors and explains how the  $V_{\text{CORE}}$  supply domain is configured depending on the operating modes, the selected performance (clock frequency) and the voltage scaling.

### 6.2 PWR main features

- Power supplies and supply domains
  - Core domains ( $V_{\text{CORE}}$ )
  - $V_{\text{DD}}$  domain
  - Backup domain ( $V_{\text{SW}}$ ,  $V_{\text{BKP}}$ )
  - Analog domain ( $V_{\text{DDA}}$ )
- System supply voltage regulation
  - Voltage regulator (LDO)
- Peripheral supply regulation
  - USB regulator
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - $V_{\text{BAT}}$  thresholds
  - Temperature thresholds
- Power management
  - $V_{\text{BAT}}$  battery charging
  - Operating modes
  - Voltage scaling control
  - Low-power modes

### 6.3 PWR block diagram

Figure 12. Power control block diagram

### 6.3.1 PWR pins and internal signals

[Table 24](#) lists the PWR inputs and output signals connected to package pins or balls, while [Table 25](#) shows the internal PWR signals.

**Table 24. PWR input/output signals connected to package pins or balls**

Pin name	Signal type	Description
V <sub>DD</sub>	Supply input	Main I/O and V <sub>DD</sub> domain supply input
V <sub>DDA</sub>	Supply input	External analog power supply for analog peripherals
V <sub>REF+</sub> , V <sub>REF-</sub>	Supply Input/Outputs	External reference voltage for ADCs and DAC
V <sub>BAT</sub>	Supply input	Backup battery supply input
V <sub>DDLDO</sub>	Supply input	Voltage regulator supply input
V <sub>CAP</sub>	Supply Input/Output	Digital core domain supply
V <sub>DD50USB</sub>	Supply input	USB regulator supply input
V <sub>DD33USB</sub>	Supply Input/Output	USB regulator supply output
V <sub>SS</sub>	Supply input	Main ground
AHB	Digital inputs/outputs	AHB register interface
PDR_ON	Digital input	Power Down Reset enable

**Table 25. PWR internal input/output signals**

Signal name	Signal type	Description
pwr_pvd_wkup	Digital output	Programmable voltage detector output
pwr_avd_wkup	Digital output	Analog voltage detector output
pwr_wkupx_wkup	Digital output	CPU wakeup signals (x=1 to 6)

Table 25. PWR internal input/output signals (continued)

Signal name	Signal type	Description
pwr_por_rst	Digital output	Power-on reset
pwr_bor_rst	Digital output	Brownout reset
exti_c_wkup	Digital input	CPU wakeup request
exti_d3_wkup	Digital input	D3 domain wakeup request
pwr_d1_wkup	Digital output	D1 domain bus matrix clock wakeup request
pwr_d2_wkup	Digital output	D2 domain bus matrix clock wakeup request
pwr_d3_wkup	Digital output	D3 domain bus matrix clock wakeup request

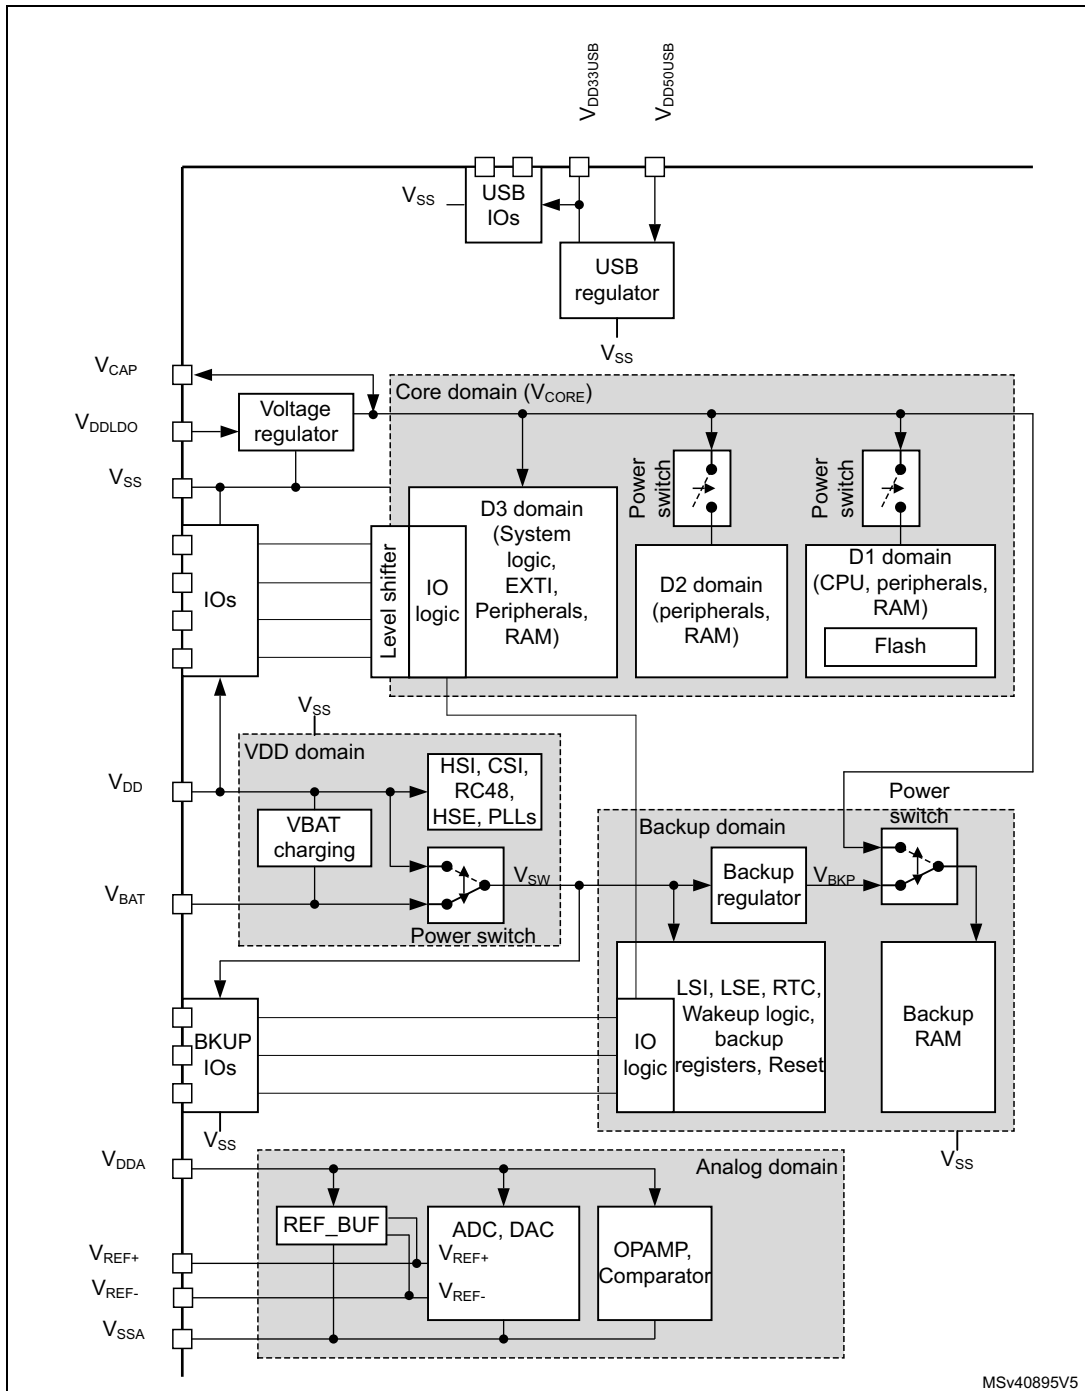

## 6.4 Power supplies

The device requires  $V_{DD}$  power supply as well as independent supplies for  $V_{DDLDO}$ ,  $V_{DDA}$ ,  $V_{DDUSB}$ , and  $V_{CAP}$ . It also provides regulated supplies for specific functions (voltage regulator, USB regulator).

- $V_{DD}$  external power supply for I/Os and system analog blocks such as reset, power management and oscillators
- $V_{BAT}$  optional external power supply for backup domain when  $V_{DD}$  is not present ( $V_{BAT}$  mode)  
This power supply shall be connected to  $V_{DD}$  when no battery is used.
- $V_{DDLDO}$  external power supply for voltage regulator
- $V_{CAP}$  digital core domain supply  
This power supply is independent from all the other power supplies:
  - When the voltage regulator is enabled,  $V_{CORE}$  is delivered by the internal voltage regulator.
  - When the voltage regulator is disabled,  $V_{CORE}$  is delivered by an external power supply through  $V_{CAP}$  pin.
- $V_{DDA}$  external analog power supply for ADCs, DACs, OPAMPs, comparators and voltage reference buffers  
This power supply is independent from all the other power supplies.
- $V_{REF+}$  external reference voltage for ADC and DAC.
  - When the voltage reference buffer is enabled,  $V_{REF+}$  and  $V_{REF-}$  are delivered by the internal voltage reference buffer.
  - When the voltage reference buffer is disabled,  $V_{REF+}$  is delivered by an independent external reference supply.
- $V_{SSA}$  separate analog and reference voltage ground.
- $V_{DD50USB}$  external power supply for USB regulator.
- $V_{DD33USB}$  USB regulator supply output for USB interface.
  - When the USB regulator is enabled,  $V_{DD33USB}$  is delivered by the internal USB regulator.
  - When the USB regulator is disabled,  $V_{DD33USB}$  is delivered by an independent external supply input.
- $V_{SS}$  common ground for all supplies and analog regulator.

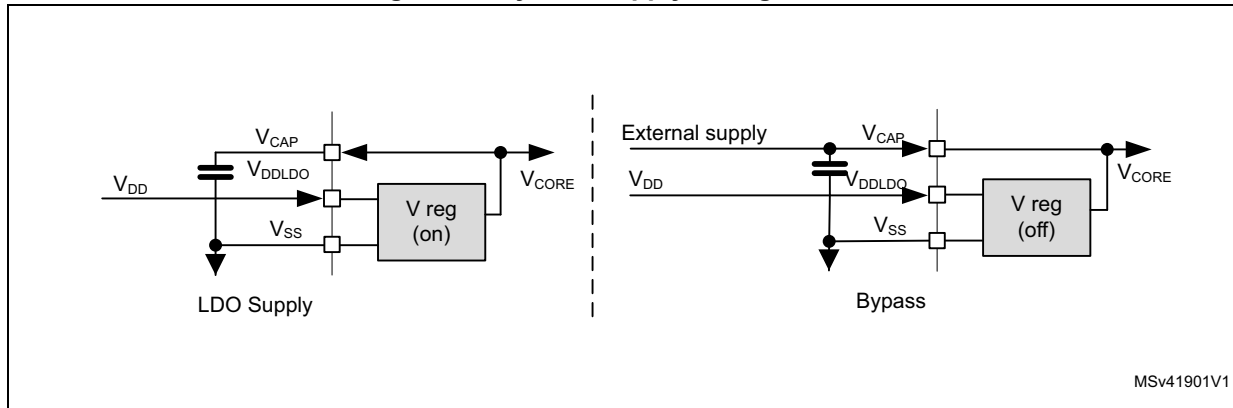

*Note:* Depending on the operating power supply range, some peripherals might be used with limited features and performance. For more details, refer to section “General operating conditions” of the device datasheets.

Figure 13. Power supply overview

By configuring the voltage regulator the supply configurations shown in [Figure 14](#) are supported for the  $V_{CORE}$  core domain and an external supply.

**Figure 14. System supply configurations**

The different supply configurations are controlled through the LDOEN and BYPASS bits in [PWR control register 3 \(PWR\\_CR3\)](#) register according to [Table 26](#).

**Table 26. Supply configuration control**

Supply configuration	LDOEN	BYPASS	Description
Default configuration	1	0	– $V_{CORE}$ Power Domains are supplied from the LDO according to VOS.
LDO supply	1	0	– $V_{CORE}$ Power Domains are supplied from the LDO according to VOS. – LDO power mode (Main, LP, Off) will follow system low-power modes.
LDO Bypass	0	1	– $V_{CORE}$ supplied from external source – LDO bypassed, voltage monitoring still active.
Illegal	0	0	– Illegal combination, the default configuration is kept. (write data will be ignored).
	1	1	

### 6.4.1 System supply startup

The system startup sequence from power-on in different supply configurations is the following (see [Figure 15](#) for LDO supply):

1. When the system is powered on, the POR monitors  $V_{DD}$  supply. Once  $V_{DD}$  is above the POR threshold level, the voltage regulator is enabled in the default supply configuration:
  - The Voltage converter output level is set at 1.0 V in accordance with the VOS3 level configured in [PWR D3 domain control register \(PWR\\_D3CR\)](#).
2. The system is kept in reset mode as long as  $V_{CORE}$  is not correct.
3. Once  $V_{CORE}$  is correct, the system is taken out of reset and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: Flash memory and option bytes are loaded and the CPU starts in limited run mode (Run\*).
5. The software shall then initialize the system including supply configuration programming in [PWR control register 3 \(PWR\\_CR3\)](#). Once the supply configuration has been configured, the ACTVOSRDY bit in [PWR control status register 1 \(PWR\\_CSR1\)](#) shall be checked to guarantee valid voltage levels:
  - a) As long as ACTVOSRDY indicates that voltage levels are invalid, the system is in Run\* mode, write accesses to the RAMs are not permitted and VOS shall not be changed.
  - b) Once ACTVOSRDY indicates that voltage levels are valid, the system is in normal Run mode, write accesses to RAMs are allowed and VOS can be changed.

The software has to program the supply configuration in [PWR control register 3 \(PWR\\_CR3\)](#).

Figure 15. Device startup with V<sub>CORE</sub> supplied from voltage regulator

1. In Run\* mode, write operations to RAM are not allowed.
2. Write operations to RAM are allowed and VOS can be changed only when ACTVOSRDY is valid.

When exiting from Standby mode, the supply configuration is known by the system since the [PWR control register 3 \(PWR\\_CR3\)](#) register content is retained. However the software shall still wait for the ACTVOSRDY bit to be set in [PWR control status register 1 \(PWR\\_CSR1\)](#) to indicate V<sub>CORE</sub> voltage levels are valid, before performing write accesses to RAM or changing VOS.

### 6.4.2 Core domain

The V<sub>CORE</sub> core domain supply can be provided by the voltage regulator or by an external supply (V<sub>CAP</sub>). V<sub>CORE</sub> supplies all the digital circuitries except for the backup domain and the Standby circuitry. The V<sub>CORE</sub> domain is split into 3 sections:

- D1 domain containing the CPU (Cortex<sup>®</sup>-M7), Flash memory and peripherals.
- D2 domain containing peripherals.
- D3 domain containing the system control, I/O logic and low-power peripherals.

When a system reset occurs, the voltage regulator is enabled and supplies  $V_{\text{CORE}}$ . This allows the system to start up in any supply configurations (see [Figure 14](#)).

After a system reset, the software shall configure the used supply configuration in [PWR control register 3 \(PWR\\_CR3\)](#) register before changing VOS in [PWR D3 domain control register \(PWR\\_D3CR\)](#) or the RCC `ck_sys` frequency. The different system supply configurations are controlled as shown in [Table 26](#).

### Voltage regulator

The embedded voltage regulator (LDO) requires external capacitors to be connected to  $V_{\text{CAP}}$  pins.

The voltage regulator provides three different operating modes: Main (MR), Low-power (LP) or Off. These modes will be used depending on the system operating modes (Run, Stop and Standby).

- Run mode

The LDO regulator is in Main mode and provides full power to the  $V_{\text{CORE}}$  domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS1, VOS2, and VOS3) that are configured through VOS bits in [PWR D3 domain control register \(PWR\\_D3CR\)](#). The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS3 is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode

The voltage regulator supplies the  $V_{\text{CORE}}$  domain to retain the content of registers and internal memories.

The regulator can be kept in Main mode to allow fast exit from Stop mode, or can be set in LP mode to obtain a lower  $V_{\text{CORE}}$  supply level and extend the exit-from-Stop latency. The regulator mode is selected through the SVOS and LPDS bits in [PWR control register 1 \(PWR\\_CR1\)](#). Main mode and LP mode are allowed if SVOS3 voltage scaling is selected, while only LP mode is possible for SVOS4 and SVOS5 scaling. Due to a lower voltage level for SVOS4 and SVOS5 scaling, the Stop mode consumption can be further reduced.

- Standby mode

The voltage regulator is OFF and the  $V_{\text{CORE}}$  domains are powered down. The content of the registers and memories is lost except for the Standby circuitry and the backup domain.

*Note:* For more details, refer to the voltage regulator section in the datasheets.

### 6.4.3 PWR external supply

When  $V_{\text{CORE}}$  is supplied from an external source, different operating modes can be used depending on the system operating modes (Run, Stop or Standby):

- In Run mode

The external source supplies full power to the  $V_{\text{CORE}}$  domain (core, memories and digital peripherals). The external source output voltage is scalable through different voltage levels (VOS1, VOS2 and VOS3). The externally applied voltage level shall be

reflected in the VOS bits of PWR\_D3CR register. The RAMs shall only be accessed for write operations when the external applied voltage level matches VOS settings.

- In Stop mode  
The external source supplies  $V_{CORE}$  domain to retain the content of registers and internal memories. The regulator can select a lower  $V_{CORE}$  supply level to reduce the consumption in Stop mode.
- In Standby mode  
The external source shall be switched OFF and the  $V_{CORE}$  domains powered down. The content of registers and memories is lost except for the Standby circuitry and the backup domain. The external source shall be switched ON when exiting Standby mode.

#### 6.4.4 Backup domain

To retain the content of the backup domain (RTC, backup registers and backup RAM) when  $V_{DD}$  is turned off,  $V_{BAT}$  pin can be connected to an optional standby voltage which is supplied from a battery or from an another source.

The switching to  $V_{BAT}$  is controlled by the power-down reset embedded in the Reset block that monitors the  $V_{DD}$  supply.

---

**Warning:** During  $t_{RSTTEMPO}$  (temporization at  $V_{DD}$  startup) or after a PDR is detected, the power switch between  $V_{BAT}$  and  $V_{DD}$  remains connected to  $V_{BAT}$ .  
During the a startup phase, if  $V_{DD}$  is established in less than  $t_{RSTTEMPO}$  (see the datasheet for the value of  $t_{RSTTEMPO}$ ) and  $V_{DD} > V_{BAT} + 0.6 V$ , a current may be injected into  $V_{BAT}$  through an internal diode connected between  $V_{DD}$  and the power switch ( $V_{BAT}$ ).  
If the power supply/battery connected to the  $V_{BAT}$  pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the  $V_{BAT}$  pin.

---

When the  $V_{DD}$  supply is present, the backup domain is supplied from  $V_{DD}$ . This allows saving  $V_{BAT}$  power supply battery life time.

If no external battery is used in the application, it is recommended to connect  $V_{BAT}$  externally to  $V_{DD}$  through a 100 nF external ceramic capacitor.

When the  $V_{DD}$  supply is present and higher than the PDR threshold, the backup domain is supplied by  $V_{DD}$  and the following functions are available:

- PC14 and PC15 can be used either as GPIO or as LSE pins.
- PC13 can be used either as GPIO or as RTC\_AF1 or RTC\_TAMP1 pin assuming they have been configured by the RTC.
- PI8/RTC\_TAMP2 and PC1/RTC\_TAMP3 when they are configured by the RTC as tamper pins.

*Note:* Since the switch only sinks a limited amount of current, the use of PC1, PC13 to PC15 and PI8 GPIOs is restricted: only one I/O can be used as an output at a time, at a speed limited to 2 MHz with a maximum load of 30 pF. These I/Os must not be used as current sources (e.g. to drive an LED).

In  $V_{BAT}$  mode, when the  $V_{DD}$  supply is absent and a supply is present on  $V_{BAT}$ , the backup domain is supplied by  $V_{BAT}$  and the following functions are available:

- PC14 and PC15 can be used as LSE pins only.
- PC13 can be used as RTC\_AF1 or RTC\_TAMP1 pin assuming they have been configured by the RTC.
- PI8/RTC\_TAMP2 and PC1/RTC\_TAMP3 when they are configured by the RTC as tamper pins.

### Accessing the backup domain

After reset, the backup domain (RTC registers and RTC backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, set the DBP bit in the [PWR control register 1 \(PWR\\_CR1\)](#).

For more detail on RTC and backup RAM access, refer to [Section 8: Reset and Clock Control \(RCC\)](#).

### Backup RAM

The backup domain includes 4 Kbytes of backup RAM accessible in 32-bit, 16-bit or 8-bit data mode. The backup RAM is supplied from the Backup regulator in the backup domain. When the Backup regulator is enabled through BREN bit in [PWR control register 2 \(PWR\\_CR2\)](#), the backup RAM content is retained even in Standby and/or  $V_{BAT}$  mode (it can be considered as an internal EEPROM if  $V_{BAT}$  is always present.)

The Backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or  $V_{BAT}$  modes.

The backup RAM is not mass erased by a tamper event, instead it is read protected to prevent confidential data, such as cryptographic private key, from being accessed. To regain access to the backup RAM after a tamper event, the memory area needs to be first erased. The backup RAM can be erased:

- through the Flash interface when a protection level change from level 1 to level 0 is requested (refer to the description of Read protection (RDP) in the Flash programming manual).
- After a tamper event, by performing a dummy write with zero as data to the backup RAM.

Figure 16. Backup domain

### 6.4.5 V<sub>BAT</sub> battery charging

When V<sub>DD</sub> is present, the external battery connected to V<sub>BAT</sub> can be charged through an internal resistance.

V<sub>BAT</sub> charging can be performed either through a 5 kΩ resistor or through a 1.5 kΩ resistor, depending on the VBRS bit value in [PWR control register 3 \(PWR\\_CR3\)](#).

The battery charging is enabled by setting the VBE bit in [PWR control register 3 \(PWR\\_CR3\)](#). It is automatically disabled in V<sub>BAT</sub> mode.

### 6.4.6 Analog supply

#### Separate V<sub>DDA</sub> analog supply

The analog supply domain is powered by dedicated V<sub>DDA</sub> and V<sub>SSA</sub> pads that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC and DAC conversion accuracy:

- The analog supply voltage input is available on a separate V<sub>DDA</sub> pin.
- An isolated supply ground connection is provided on V<sub>SSA</sub> pin.

#### Analog reference voltage V<sub>REF+</sub>/V<sub>REF-</sub>

To achieve better accuracy low-voltage signals, the ADC and DAC also have a separate reference voltage, available on V<sub>REF+</sub> pin. The user can connect a separate external reference voltage on V<sub>REF+</sub>.

The V<sub>REF+</sub> controls the highest voltage, represented by the full scale value, the lower voltage reference (V<sub>REF-</sub>) being connected to V<sub>SSA</sub>.

When enabled by ENVR bit in the VREFBUF control and status register (see [Section 27: Voltage reference buffer \(VREFBUF\)](#)),  $V_{REF+}$  is provided from the internal voltage reference buffer. The internal voltage reference buffer can also deliver a reference voltage to external components through  $V_{REF+}/V_{REF-}$  pins.

When the internal voltage reference buffer is disabled by ENVR,  $V_{REF+}$  is delivered by an independent external reference supply voltage.

### 6.4.7 USB regulator

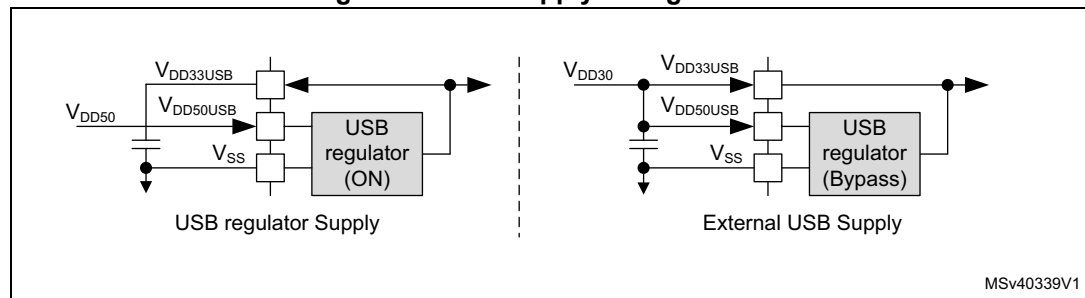

The USB transceivers are supplied from a dedicated  $V_{DD33USB}$  supply that can be provided either by the integrated USB regulator, or by an external USB supply.

When enabled by USBREGEN bit in [PWR control register 3 \(PWR\\_CR3\)](#), the  $V_{DD33USB}$  is provided from the USB regulator. Before using  $V_{DD33USB}$ , check that it is available by monitoring USB33RDY bit in [PWR control register 3 \(PWR\\_CR3\)](#). The  $V_{DD33USB}$  supply level detector shall be enabled through USB33DEN bit in PWR\_CR3 register.

When the USB regulator is disabled through USBREGEN bit,  $V_{DD33USB}$  can be provided from an external supply. In this case  $V_{DD33USB}$  and  $V_{DD50USB}$  shall be connected together.

For more information on the USB regulator (see [Section 57: USB on-the-go high-speed \(OTG\\_HS\)](#)).

Figure 17. USB supply configurations

## 6.5 Power supply supervision

Power supply level monitoring is available on the following supplies:

- $V_{DD}$  via POR/PDR (see [Section 6.5.1](#)), BOR (see [Section 6.5.2](#)) and PVD monitor (see [Section 6.5.3](#))
- $V_{DDA}$  via AVD monitor (see [Section 6.5.4](#))
- $V_{BAT}$  via VBAT threshold (see [Section 6.5.5](#))
- $V_{SW}$  via rst\_vsw, which keeps  $V_{SW}$  domain in Reset mode as long as the level is not OK.
- $V_{BKP}$  via a BRRDY bit in [PWR control register 2 \(PWR\\_CR2\)](#).
- $V_{DD33USB}$  via USBRDY bit in [PWR control register 3 \(PWR\\_CR3\)](#).

### 6.5.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in Reset mode when  $V_{DD}$  is below a specified  $V_{POR}$  threshold, without the need for an external reset circuit. Once the  $V_{DD}$  supply level is above the  $V_{POR}$  threshold, the system is taken out of reset (see [Figure 18](#)). For more details concerning the power-on/power-down reset threshold, refer to the electrical characteristics section of the datasheets.

The PDR can be enabled/disabled by the device PDR\_ON input pin.

**Figure 18. Power-on reset/power-down reset waveform**

1. For thresholds and hysteresis values, please refer to the datasheets.

### 6.5.2 Brownout reset (BOR)

During power-on, the Brownout reset (BOR) keeps the system under reset until the  $V_{DD}$  supply voltage reaches the specified  $V_{BOR}$  threshold.

The  $V_{BOR}$  threshold is configured through system option bytes. By default, BOR is OFF. The following programmable  $V_{BOR}$  thresholds can be selected:

- BOR OFF ( $V_{BOR0}$ )
- BOR Level 1 ( $V_{BOR1}$ )
- BOR Level 2 ( $V_{BOR2}$ )
- BOR Level 3 ( $V_{BOR3}$ )

For more details on the brown-out reset thresholds, refer to the section “Electrical characteristics” of the product datasheets.

A system reset is generated when the BOR is enabled and  $V_{DD}$  supply voltage drops below the selected  $V_{BOR}$  threshold.

BOR can be disabled by programming the system option bytes. To disable the BOR function,  $V_{DD}$  must have been higher than  $V_{BOR0}$  to start the system option byte programming sequence. The power-down is then monitored by the PDR (see [Section 6.5.1](#)).

Figure 19. BOR thresholds

1. For thresholds and hysteresis values, please refer to the datasheets.

### 6.5.3 Programmable voltage detector (PVD)

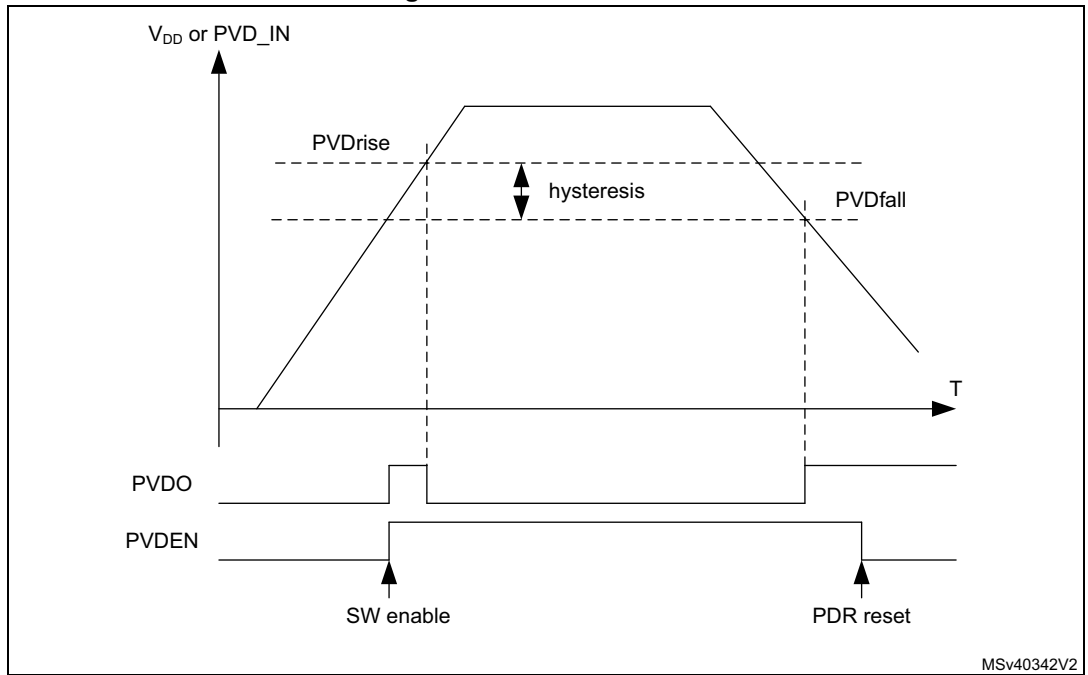

The PVD can be used to monitor the  $V_{DD}$  power supply by comparing it to a threshold selected by the PLS[2:0] bits in the [PWR control register 1 \(PWR\\_CR1\)](#). The PVD can also be used to monitor a voltage level on the PVD\_IN pin. In this case PVD\_IN voltage is compared to the internal  $V_{REFINT}$  level.

The PVD is enabled by setting the PVDE bit in [PWR control register 1 \(PWR\\_CR1\)](#).

A PVDO flag is available in the [PWR control status register 1 \(PWR\\_CSR1\)](#) to indicate whether  $V_{DD}$  or PVD\_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, assuming it has been enabled through the EXTI registers. The pwr\_pvd\_wkup output interrupt can be generated when  $V_{DD}$  or PVD\_IN voltage drops below the PVD threshold and/or when  $V_{DD}$  or PVD\_IN voltage rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

Figure 20. PVD thresholds

1. For thresholds and hysteresis values, please refer to the datasheets.

### 6.5.4 Analog voltage detector (AVD)

The AVD can be used to monitor the  $V_{DDA}$  supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR\_CR1)*.

The AVD is enabled by setting the AVDEN bit in *PWR control register 1 (PWR\_CR1)*.

An AVDO flag is available in the *PWR control status register 1 (PWR\_CSR1)* to indicate whether  $V_{DDA}$  is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The `pwr_avd_wkup` interrupt can be generated when  $V_{DDA}$  drops below the AVD threshold and/or when  $V_{DDA}$  rises above the AVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could indicate when the  $V_{DDA}$  supply drops below a minimum level.

Figure 21. AVD thresholds

1. For thresholds and hysteresis values, please refer to the datasheets.

### 6.5.5 Battery voltage thresholds

The  $V_{BAT}$  battery voltage supply can be monitored by comparing it with two threshold levels:  $V_{BAThigh}$  and  $V_{BATlow}$ . VBATH and VBATL flags in the *PWR control register 2 (PWR\_CR2)*, indicate if  $V_{BAT}$  is higher or lower than the threshold. The  $V_{BAT}$  supply monitoring can be enabled/disabled via MONEN bit in *PWR control register 2 (PWR\_CR2)*. When it is enabled, the battery voltage thresholds increase power consumption. As an example the levels could be used to trigger a routine to perform emergency saving tasks.

VBATH and VBATL wakeup interrupts are available on the RTC tamper signals (see *Section 46: Real-time clock (RTC)*)

Figure 22. VBAT thresholds

1. For thresholds and hysteresis values, please refer to the datasheets.

### 6.5.6 Temperature thresholds

The junction temperature can be monitored by comparing it with two threshold levels,  $TEMP_{high}$  and  $TEMP_{low}$ .  $TEMPH$  and  $TEMPL$  flags, in the *PWR control register 2 (PWR\_CR2)*, indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via  $MONEN$  bit in *PWR control register 2 (PWR\_CR2)*. When enabled, the temperature thresholds increase power consumption. As an example the levels could be used to trigger a routine to perform temperature control tasks.

$TEMPH$  and  $TEMPL$  wakeup interrupts are available on the RTC tamper signals (see *Section 46: Real-time clock (RTC)*).

Figure 23. Temperature thresholds

MSv40345V1

1. For thresholds and hysteresis values, please refer to the datasheets.

## 6.6 Power management

The power management block controls the  $V_{CORE}$  supply in accordance with the system operation modes (see [Section 6.6.1](#)).

The  $V_{CORE}$  domain is split into the following power domains.

- D1 domain containing some peripherals and the Cortex<sup>®</sup>-M7 Core (CPU).
- D2 domain containing a large part of the peripherals.
- D3 domain containing some peripherals and the system control.

The D1, D2 and system D3 power domains can operate in one of the following operating modes:

- DRun/Run/Run\* (power ON, clock ON)
- DStop/Stop (power ON, clock OFF)
- DStandby/Standby (Power OFF, clock OFF).

The operating modes for D1 domain and D2 domain are independent. However system D3 domain power modes depend on D1 and D2 domain modes:

- For system D3 domain to operate in Stop mode, both D1 and D2 domains must be in DStop or DStandby mode.
- For system D3 domain to operate in Standby mode, both D1 and D2 domains must be in DStandby too.

D1, D2 and system D3 domains are supplied from a single regulator at a common  $V_{CORE}$  level. The  $V_{CORE}$  supply level follows the system operating mode (Run, Stop, Standby). The D1 domain and/or D2 domain supply can be powered down individually when the domains are in DStandby mode.

The following voltage scaling features allow controlling the power with respect to the required system performance (see [Section 6.6.2: Voltage scaling](#)):

- To obtain a given system performance, the corresponding voltage scaling shall be set in accordance with the system clock frequency. To do this, configure the VOS bits to the Run mode voltage scaling.
- To obtain the best trade-off between power consumption and exit-from-Stop mode latency, configure the SVOS bits to Stop mode voltage scaling.

## 6.6.1 Operating modes

Several system operating modes are available to tune the system according to the performance required, i.e. when the CPU does not need to execute code and is waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low power consumption, short startup time and available wakeup sources.

The operating modes allow controlling the clock distribution to the different system blocks and powering them. The system operating mode is driven by the CPU subsystem, D2 domain and system D3 autonomous wakeup. The CPU subsystem can include multiple domains depending on its peripheral allocation (see [Section 8.5.11: Peripheral clock gating control](#)).

The following operating modes are available for the different system blocks (see [Table 27](#)):

- CPU subsystem modes:
  - **CRun**  
CPU and CPU subsystem peripheral(s) allocated via RCC PERxEN bits are clocked.
  - **CSleep:**  
The CPU clocks is stalled and the CPU subsystem allocated peripheral(s) clock operate according to RCC PERxLPEN.
  - **CStop:**  
CPU and CPU subsystem peripheral(s) clocks are stalled.
- D1 domain mode:
  - DRun  
The domain bus matrix is clocked. The CPU subsystem operates in CRun or CSleep mode.
  - DStop  
The domain bus matrix clock is stalled.  
The CPU subsystem operates in CStop mode and the PDDS\_D1<sup>(1)</sup> bit selects DStop mode.
  - DStandby  
The domain is powered down.  
The CPU subsystem operates in CStop mode and the PDDS\_D1 bit selects DStandby mode.
- D2 domain mode:
  - DRun  
The domain bus matrix is clocked.  
The CPU subsystem has an allocated peripheral in the D2 domain and the CPU subsystem operates in CRun or CSleep mode.

---

1. The PDDS\_Dn bits belong to [PWR CPU control register \(PWR\\_CPUCR\)](#).

- DStop
  - The domain bus matrix clock is stalled.
  - The CPU subsystem has no peripherals allocated in the D2 domain and PDDS\_D2<sup>(1)</sup> bit selects DStop mode,
  - or
  - the CPU subsystem has an allocated peripheral in D2 domain, the CPU subsystem operates in CStop mode and PDDS\_D2 bit selects DStop mode.
- DStandby
  - The domain is powered down.
  - The CPU subsystem has no peripherals allocated in the D2 domain and PDDS\_D2 bit selects DStandby mode,
  - or
  - the CPU subsystem has an allocated peripheral in the D2 domain, the CPU subsystem operates in CStop mode and PDDS\_D2 bit selects DStandby mode.
- System /D3 domain modes
  - **Run/Run\***
    - The system clock and D3 domain bus matrix clock are running:
      - The CPU subsystem is in CRun or CSleep mode
      - or
      - A wakeup signal is active. (i.e. System D3 autonomous mode)
    - The Run\* mode is entered after a POR reset and a wakeup from Standby. In Run\* mode, the performance is limited and the system supply configuration shall be programmed in [PWR control register 3 \(PWR\\_CR3\)](#). The system enters Run mode only when the ACTVOSRDY bit in [PWR control status register 1 \(PWR\\_CSR1\)](#) is set to 1.
  - **Stop**
    - The system clock and D3 domain bus matrix clock is stalled:
      - The CPU subsystem is in CStop mode.
      - and
      - all wakeup signals are inactive.
      - and
      - At least one PDDS\_Dn<sup>(1)</sup> bit for any domain select Stop mode.
  - **Standby**
    - The system is powered down:
      - The CPU subsystem is in CStop mode
      - and
      - all wakeup signals are inactive.
      - and
      - All PDDS\_Dn<sup>(1)</sup> bits for all domains select Standby mode.

In Run mode, power consumption can be reduced by one of the following means:

- Lowering the system performance by slowing down the system clocks and reducing the V<sub>CORE</sub> supply level through VOS voltage scaling bits.
- Gating the clocks to the APBx and AHBx peripherals when they are not used, through PERxEN bits.

Table 27. Low-power mode summary

System	Domain	CPU	Entry	Wakeup	Sys-oscillator	System clk	Domain bus matrix clk	Peripheral clk	CPU clk	Voltage regulator	Domain supply	
Run	DRun <sup>(1)</sup>	CRun	-	-	ON	ON	ON	ON	ON	ON	ON	
		CSleep	WFI or return from ISR or WFE	Any interrupt or event				ON/OFF <sup>(2)</sup>				
	DStop <sup>(3)</sup>	CStop	DStandby <sup>(3)</sup>	SLEEPDEEP bit + WFI or return from ISR or WFE	Any EXTI interrupt or event	ON/OFF <sup>(7)</sup>	OFF	OFF	ON/OFF <sup>(4)</sup>	OFF	ON	OFF
												DStop <sup>(3)</sup>
Stop <sup>(5)</sup>	DStop <sup>(3)</sup>		DStandby <sup>(3)</sup>	SLEEPDEEP bit + WFI or return from ISR or WFE or Wakeup source cleared <sup>(6)</sup>	Any EXTI interrupt or event	ON/OFF <sup>(7)</sup>	OFF	OFF	ON/OFF <sup>(4)</sup>	OFF	ON	ON
												DStandby <sup>(3)</sup>
Standby <sup>(8)</sup>	DStandby <sup>(3)</sup>		All PDDS_Dn bit + SLEEPDEEP bit + WFI or return from ISR or WFE or Wakeup source cleared <sup>(6)</sup>	WKUP pins rising or falling edge, RTC alarm (Alarm A or Alarm B), RTC Wakeup event, RTC tamper events, RTC time stamp event, external reset in NRST pin, IWDG reset	OFF	OFF	OFF	OFF	OFF	OFF		

1. The CPU subsystem has an allocated peripheral in the D2 domain and operates in CRun or CSleep mode.
2. The CPU subsystem peripherals that have a PERxLPEN bit will operate accordingly.
3. If the CPU subsystem has an allocated peripheral in the D2 domain, it must operate in CStop mode.
4. The CPU subsystem peripherals that have a PERxAMEN bit will operate accordingly.
5. All domains need to be in DStop Or DStandby.
6. When the CPU is in CStop and D3 domain in autonomous mode, the last EXTI Wakeup source is cleared.
7. When the system oscillator HSI or CSI is used, the state is controlled by HSIKERON and CSIKERON, otherwise the system oscillator is OFF.
8. All domains are in DStandby mode.

### 6.6.2 Voltage scaling

The D1, D2, and D3 domains are supplied from a single voltage regulator supporting voltage scaling with the following features:

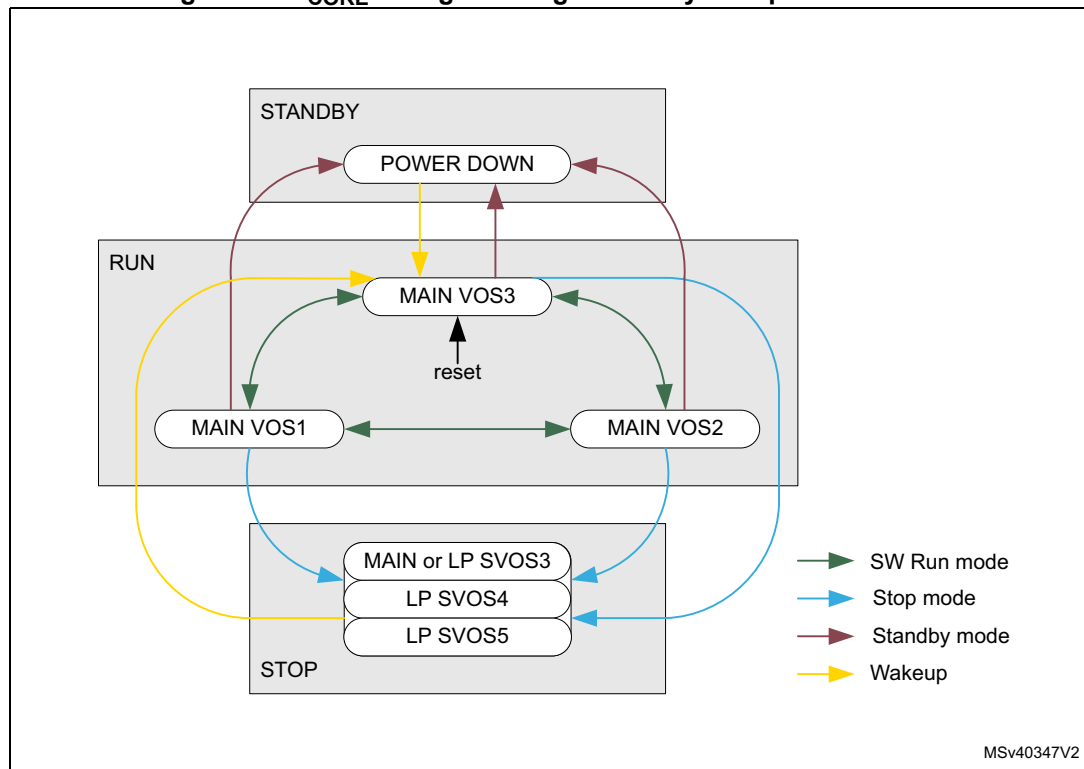

- Run mode voltage scaling
  - VOS1: Scale 1
  - VOS2: Scale 2
  - VOS3: Scale 3
- Stop mode voltage scaling
  - SVOS3: Scale 3
  - LP-SVOS4: Scale 4
  - LP-SVOS5: Scale 5

For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS3). The voltage scaling can then be changed on-the-fly by software by programming VOS bits in *PWR D3 domain control register (PWR\_D3CR)* according to the required system performance. When exiting from Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS3 value.

Before entering Stop mode, the software can preselect the SVOS level in *PWR control register 1 (PWR\_CR1)*. The Stop mode voltage scaling for SVOS4 and SVOS5 also sets the voltage regulator in Low-power (LP) mode to further reduce power consumption. When preselecting SVOS3, the use of the voltage regulator low-power mode (LP) can be selected by LPDS register bit.

Figure 24. V<sub>CORE</sub> voltage scaling versus system power modes

MSv40347V2

### 6.6.3 Power control modes

The power control block handles the  $V_{CORE}$  supply for system Run, Stop and Standby modes.

The system operating mode depends on the CPU subsystem modes (CRun, CSleep, CStop), on the domain modes (DRun, DStop, DStandby), and on the system D3 autonomous wakeup:

- In Run mode,  $V_{CORE}$  is defined by the VOS voltage scaling.  
The CPU subsystem is in CRun or CSleep or an EXTI wakeup is active.
- In Stop mode,  $V_{CORE}$  is defined by the SVOS voltage scaling.  
The CPU subsystem is in CStop mode and all EXTI wakeups are inactive. The D1 domain and D2 domain are either in DStop or DStandby mode.
- In Standby mode,  $V_{CORE}$  supply is switched off.  
The CPU subsystem is in CStop mode and all EXTI wakeups are inactive. The D1 domain and D2 domain are both in DStandby mode.

The domain operating mode can depend on the CPU subsystem when peripherals are allocated in the corresponding domain. The domain mode selection between DStop and DStandby is configured via domain dedicated PDDS\_Dn bits in *PWR CPU control register (PWR\_CPUCR)*. The CPU can choose to keep a domain in DStop, or allow a domain to enter DStandby mode.

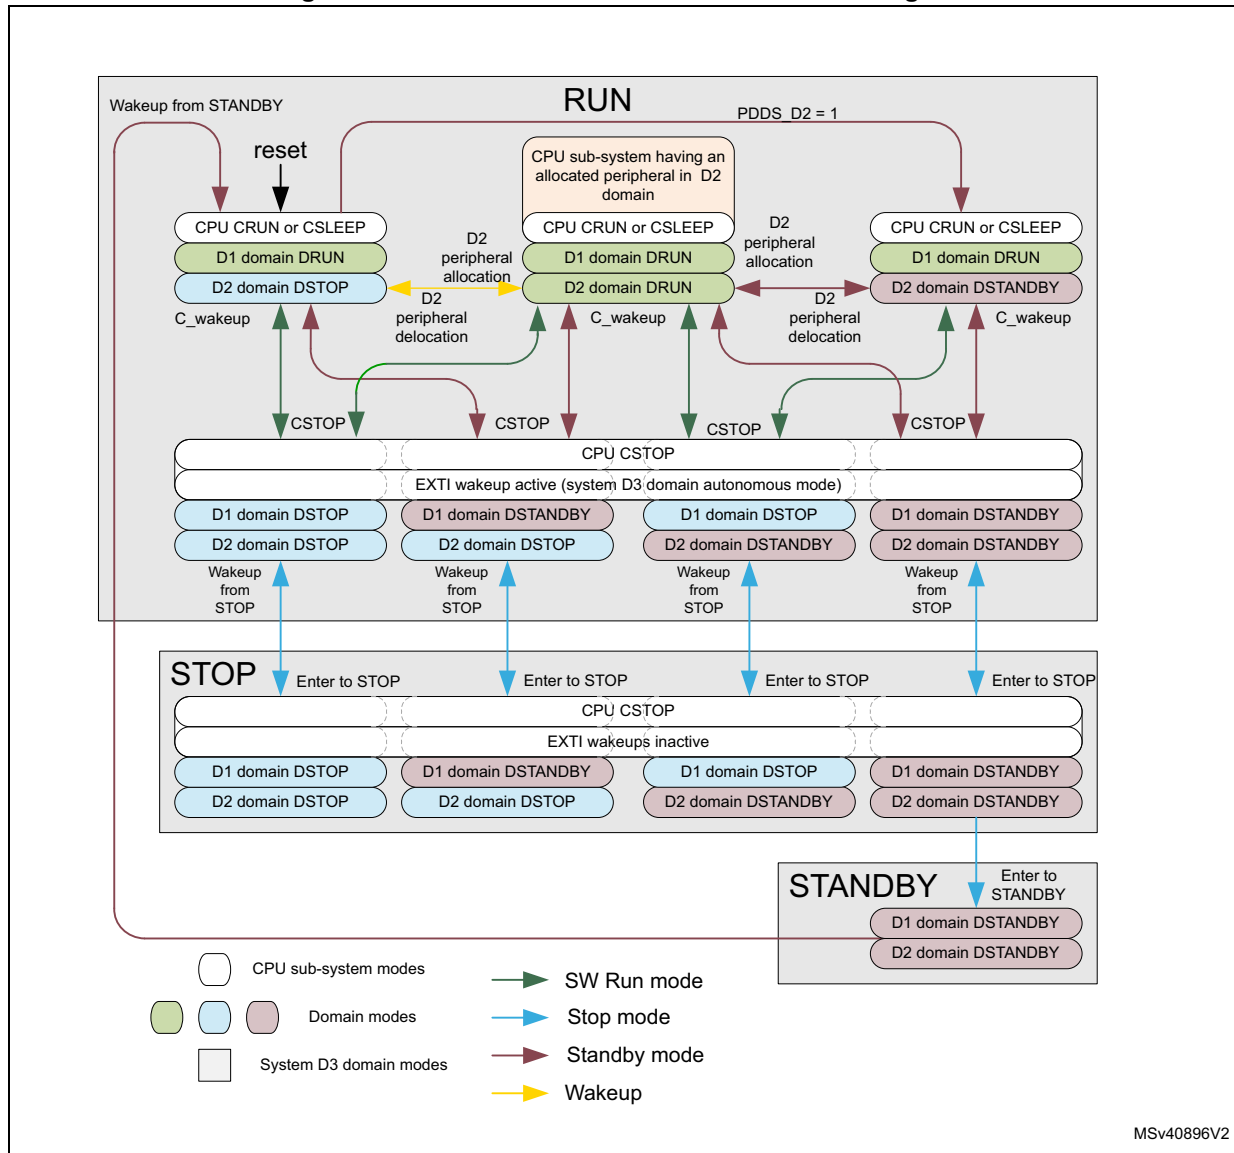

If a domain is in DStandby mode, the corresponding power is switched off.

All the domains can be configured for the system mode (Stop or Standby) through PDDS\_Dn bits in *PWR CPU control register (PWR\_CPUCR)*. The system enters Standby only when all PDDS\_Dn bits for all domains have allowed it.

**Table 28. PDDS\_Dn low-power mode control**

PWR_CPUCR			D1 mode	D2 mode	D3 mode
PDDS_D1	PDDS_D2	PDDS_D3			
0	x	x	DStop	any	Run or Stop
1			DStandby	any	any
x	0		any	DStop	Run or Stop
	1		any	DStandby	any
at least one = 0			DStop or DStandby	DStop or DStandby	Stop
1	1	1	DStandby	DStandby	Standby

Figure 25. Power control modes detailed state diagram

After a system reset, the CPU is in CRun mode.

Power control state transitions are initiated by the following events:

- CPU going to CStop mode (state transitions in Run mode are marked in green and red)
  - Green transitions: CPU wakes up as from CSleep.
  - Red transitions: CPU wakes up with domain reset. The SBF\_Dn is set.
- Allocating or de-locating a peripheral in a domain (state transitions in Run mode are marked in orange and red)
  - Orange transitions: the domain wakes up from DStop
  - Red transitions: the domain wakes up from DStandby. The SBF\_Dn is set.
- The system enters or exits from Stop mode (state transitions marked in blue)
  - Blue transitions the system wakes up from Stop mode. The STOPF is set.
- The system enters or exits from Standby mode (state transitions in Stop and Standby mode are marked in red).
  - When exiting from Standby mode, the SBF is set.

When a domain exits from DStandby, the domain peripherals are reset, while the domain SBF\_Dn bit is set (state transitions causing a domain reset are marked in red).

Table 29 shows the flags that indicate from which mode the domain/system exits. The CPU features a set of flags which can be read from *PWR CPU control register (PWR\_CPUCR)*.

**Table 29. Low-power exit mode flags**

System mode	D1 domain mode	D2 domain mode	SBF_D1	SBF_D2	SBF	STOPF	Comment
Run	DRun or DStop	DRun or DStop	0	0	0	0	D1, D2 and system contents retained
Run	DStandby	DStop	1	0	0	0	D1 contents lost, D2 and system contents retained
Run	DRun or DStop	DStandby	0	1	0	0	D2 contents lost, D1 and system contents retained
Run	DStandby	DStandby	1	1	0	0	D1 and D2 contents lost, system contents retained
Stop	DStop	DStop	0	0	0	1	D1, D2 and system contents retained, clock system reset.
Stop	DStandby	DStop	1	0	0	1	D1 contents lost, D2 and system contents retained, clock system reset
Stop	DStop	DStandby	0	1	0	1	D2 contents lost, D1 and system contents retained, clock system reset
Stop	DStandby	DStandby	1	1	0	1	D1 and D2 contents lost, system contents retained, clock system reset
Standby	DStandby	DStandby	0 <sup>(1)</sup>	0 <sup>(1)</sup>	1	0	D1, D2 and system contents lost

1. When returning from Standby, the SBF\_D1 and SBF\_D2 reflect the reset value.

## 6.6.4 Power management examples

- [Figure 26](#) shows  $V_{\text{CORE}}$  voltage scaling behavior in Run mode.
- [Figure 27](#) shows  $V_{\text{CORE}}$  voltage scaling behavior in Stop mode.
- [Figure 28](#) shows  $V_{\text{CORE}}$  voltage regulator and voltage scaling behavior in Standby mode.
- [Figure 29](#) shows  $V_{\text{CORE}}$  voltage scaling behavior in Run mode with D1 and D2 domains are in DStandby mode

### Example of $V_{\text{CORE}}$ voltage scaling behavior in Run mode

[Figure 26](#) illustrates the following system operation sequence example:

1. After reset, the system starts from HSI with VOS3.
2. The system performance is first increased to a medium-speed clock from the PLL with voltage scaling VOS2. To do this:
  - a) Program the voltage scaling to VOS2.
  - b) Once the  $V_{\text{CORE}}$  supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
  - c) Once the PLL is locked, switch the system clock.
3. The system performance is then increased to high-speed clock from the PLL with voltage scaling VOS1. To do this:
  - a) Program the voltage scaling to VOS1.
  - b) Once the  $V_{\text{CORE}}$  supply has reached the required level indicated by VOSRDY, increase the clock frequency.
4. The system performance is then reduced to a medium-speed clock with voltage scaling VOS2. To do this:
  - a) First decrease the system frequency.
  - b) Then decrease the voltage scaling to VOS2.
5. The next step is to reduce the system performance to HSI clock with voltage scaling VOS3. To do this:
  - a) Switch the clock to HSI.
  - b) Disable the PLL.
  - c) Decrease the voltage scaling to VOS3.
6. The system performance can then be increased to high-speed clock from the PLL. To do this:
  - a) Program the voltage scaling to VOS1.
  - b) Once the  $V_{\text{CORE}}$  supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
  - c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS shall be set accordingly, otherwise the system might be unreliable.

Figure 26. Dynamic voltage scaling in Run mode

MSv40350V1

1. The status of the register bits at each step is shown in blue.

### Example of V<sub>CORE</sub> voltage scaling behavior in Stop mode

Figure 27 illustrates the following system operation sequence example:

- The system is running from the PLL in high-performance mode (VOS1 voltage scaling).
- The CPU subsystem deallocates all the peripheral in the D2 domain that will first enter DStop mode. D2 system clock is stopped. The system still provides the high-performance system clock, hence the voltage scaling shall stay at VOS1 level.
- In a second step, the CPU subsystem enters CStop mode, D1 domain enters DStop mode and the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS4 level.
- The CPU subsystem is then woken up. The system exits from Stop mode, the D1 domain exits from DStop mode and the CPU subsystem exits from CStop mode. The hardware then sets the voltage scaling to VOS3 level and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock and the D1 system clock are enabled.
- The CPU subsystem allocates a peripheral in the D2 domain. The D2 system clock is enabled.
- The system performance is then increased. To do this:
  - The software first sets the voltage scaling to VOS1.
  - Once the V<sub>CORE</sub> supply has reached the required level indicated by VOSRDY, the clock frequency can be increased by enabling the PLL.
  - Once the PLL is locked, the system clock can be switched.

Figure 27. Dynamic voltage scaling behavior with D1, D2 and system in Stop mode

MSv40897V1

1. The status of the register bits at each step is shown in blue.

### Example of V<sub>CORE</sub> voltage regulator and voltage scaling behavior in Standby mode

Figure 28 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all the peripherals in the D2 domain that will first enter DStandby mode. The D2 domain bus matrix clock is stopped and the power is switched off. The system performance is unchanged hence the voltage scaling does not change.
3. The CPU subsystem then enters to CStop mode, D1 domain enters DStandby mode and the system enters Standby mode. The system clock is stopped and the voltage regulator switched off.
4. The system is then woken up by a wakeup source. The system exits from Standby mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock and D1 subsystem clock are enabled. Since there are no allocated peripherals in the D2 domain, this domain remains in

DStop mode. The software shall then check the ACTVOSRDY is valid before changing the system performance.

5. In a next step, increase the system performance. To do this:
  - a) The software first increases the voltage scaling to VOS1 level
  - b) Before enabling the PLL, it waits for the requested supply level to be reached by monitoring VOSRDY bit.
  - c) Once the PLL is locked, the system clock can be switched.
6. The CPU subsystem puts the D2 domain in DStandby mode.

Figure 28. Dynamic Voltage Scaling D1, D2, system Standby mode

1. The status of the register bits at each step is shown in blue.

### Example of $V_{CORE}$ voltage scaling behavior in Run mode with D1 and D2 domains in DStandby mode

*Figure 29* illustrates the following system operation sequence example:

1. The system is running from the PLL with system in high performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all the peripherals in the D2 domain that will first enter DStandby mode. The D2 domain bus matrix clock is stopped and its power switched off. The system performance is unchanged hence the voltage scaling does not change.
3. The CPU subsystem then enters CStop mode and the D1 domain enters DStandby mode. The D1 domain bus matrix clock is stopped and its power switched off. At the same time the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS4 level.
4. The system is then woken up by a D3 autonomous mode wakeup event. The system exits from Stop mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled. The system is running in D3 autonomous mode.
5. The D3 autonomous mode wakeup source is then cleared, causing the system to enter Stop mode. The system clock is stopped and the voltage scaling is lowered to the software preselected SVOS4 level.
6. The CPU subsystem is then woken up. The system exits from Stop mode, the D1 domain exits from DStandby mode and the CPU subsystem exits from CStop mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock and the D1 subsystem clock are enabled. The D2 domain remains in DStandby mode.

**Figure 29. Dynamic voltage scaling behavior with D1 and D2 in DStandby mode and , D3 in autonomous mode**

MSv40899V2

1. The status of the register bits at each step is shown in blue.

## 6.7 Low-power modes

Several low-power modes are available to save power when the CPU does not need to execute code (i.e. when waiting for an external event). It is up to the user application to select the mode that gives the best compromise between low power consumption, short startup time and available wakeup sources:

- Slowing down system clocks (see [Section 8.5.6: System clock \(sys\\_ck\)](#))
- Controlling individual peripheral clocks (see [Section 8.5.11: Peripheral clock gating control](#))
- Low-power modes
  - CSleep (CPU clock stopped)
  - CStop (CPU subsystem clock stopped)
  - DStop (Domain bus matrix clock stopped)
  - Stop (System clock stopped)
  - DStandby (Domain powered down)
  - Standby (System powered down)

### 6.7.1 Slowing down system clocks

In Run mode, the speed of the system clock `ck_sys` can be reduced. For more details refer to [Section 8.5.6: System clock \(sys\\_ck\)](#).

### 6.7.2 Controlling peripheral clocks

In Run mode, the HCLKx and PCLKx for individual peripherals can be stopped by configuring at any time PERxEN bit in `RCC_C1_xxxxENR` or `RCC_DnxxxxENR` to reduce power consumption.

To reduce power consumption in CSleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bit in `RCC_C1_xxxxLPENR` or `RCC_DnxxxxLPENR`. For the peripherals still receiving a clock in CSleep mode, their clock can be slowed down before entering CSleep mode.

### 6.7.3 Entering low-power modes

CPU subsystem CSleep and CStop low-power modes are entered by the MCU when executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex<sup>®</sup>-M System Control register is set on Return from ISR.

A domain can enter DStop or DStandby low-power mode when the CPU subsystem has an allocated peripheral in the domain and enters CStop mode, or when all D2 domain peripherals are deallocated.

The system can enter Stop or Standby low-power mode when all EXTI wakeup sources are cleared and the other domains are in DStop or DStandby mode.

### 6.7.4 Exiting from low-power modes

The CPU subsystem exits from CSleep mode through any interrupt or event depending on how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the CPU exits from low-power mode as soon as an event occurs. The wakeup event can be generated either by:

- An NVIC IRQ interrupt.

**When SEVONPEND = 0** in the Cortex<sup>®</sup>-M7 System Control register, the interrupt must be enabled in the peripheral control register and in the NVIC.

When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit in the NVIC interrupt clear pending register have to be cleared. Only NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

**When SEVONPEND = 1** in the Cortex<sup>®</sup>-M7 System Control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and, when enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts will wakeup the MCU, even the disabled ones.

Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

- An event

An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It might be necessary to clear the interrupt flag in the peripheral.

The CPU subsystem exits from CStop, DStop and Stop modes by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

The system can wakeup from Stop mode by enabling an EXTI wakeup, without waking up a CPU subsystem. In this case the system will operate in D3 autonomous mode.

The CPU subsystem exits from DStandby mode by enabling an EXTI interrupt or event, regardless on how DStandby mode was entered. Program execution restarts from CPU local reset (such as a reset vector fetched from System configuration block (SYSCFG)).

The D2 domain can exit from DStop or DStandby mode when the CPU allocates a first peripheral in the domain.

The CPU subsystem exits from Standby mode by enabling an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event. Program execution restarts in the same way as after a system reset (such as boot pin sampling, option bytes loading or reset vector fetched).

### 6.7.5 CSleep mode

The CSleep mode applies only to the CPU subsystem. In CSleep mode, the CPU clock is stopped. The CPU subsystem peripheral clocks operate according to the values of PERxLPEN bits in RCC\_C1\_XXXXENR or RCC\_DnXXXXENR.

#### Entering CSleep mode

The CSleep mode is entered according to [Section 6.7.3: Entering low-power modes](#), when the SLEEPDEEP bit in the Cortex<sup>®</sup>-M System Control register is cleared.

Refer to [Table 30](#) for details on how to enter to CSleep mode.

#### Exiting from CSleep mode

The CSleep mode is exited according to [Section 6.7.4: Exiting from low-power modes](#).

Refer to [Table 30](#) for more details on how to exit from CSleep mode.

**Table 30. CSleep mode**

CSleep mode	Description
<b>Mode entry</b>	WFI (Wait for Interrupt) or WFE (Wait for Event) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 0 (Refer to the Cortex<sup>®</sup>-M System Control register.)</li> <li>– CPU NVIC interrupts and events cleared.</li> </ul>
	On return from ISR while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 0 and</li> <li>– SLEEPONEXIT = 1 (refer to the Cortex<sup>®</sup>-M System Control register.)</li> <li>– CPU NVIC interrupts and events cleared.</li> </ul>
<b>Mode exit</b>	If WFI or return from ISR was used for entry: <ul style="list-style-type: none"> <li>– Any Interrupt enabled in NVIC: Refer to <a href="#">Table 130: NVIC</a></li> </ul> If WFE was used for entry and SEVONPEND = 0: <ul style="list-style-type: none"> <li>– Any event: Refer to <a href="#">Section 20.5.3: EXTI CPU wakeup procedure</a></li> </ul> If WFE was used for entry and SEVONPEND = 1: <ul style="list-style-type: none"> <li>– Any Interrupt even when disabled in NVIC: refer to <a href="#">Table 130: NVIC</a> or any event: refer to <a href="#">Section 20.5.3: EXTI CPU wakeup procedure</a></li> </ul>
<b>Wakeup latency</b>	None

### 6.7.6 CStop mode

The CStop mode applies only to the CPU subsystem. In CStop mode, the CPU clock is stopped. Most CPU subsystem peripheral clocks are stopped too and only the CPU subsystem peripherals having a PERxAMEN bit operate accordingly.

In CStop mode, the CPU subsystem peripherals that have a kernel clock request can still request their kernel clock. For the peripheral that have a PERxAMEN bit, this bit shall be set to be able to request the kernel clock.

#### Entering CStop mode

The CStop mode is entered according to [Section 6.7.3: Entering low-power modes](#), when the SLEEPDEEP bit in the Cortex<sup>®</sup>-M System Control register is set.

Refer to [Table 31](#) for details on how to enter to CStop mode.

#### Exiting from CStop mode

The CStop mode is exited according to [Section 6.7.4: Exiting from low-power modes](#).

Refer to [Table 31](#) for more details on how to exit from CStop mode.

**Table 31. CStop mode**

CStop mode	Description
<b>Mode entry</b>	WFI (Wait for Interrupt) or WFE (Wait for Event) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 1 (Refer to the Cortex<sup>®</sup>-M System Control register.)</li> <li>– CPU NVIC interrupts and events cleared.</li> <li>– All CPU EXTI Wakeup sources are cleared.</li> </ul>
	On return from ISR while: <ul style="list-style-type: none"> <li>– SLEEPDEEP = 1 and</li> <li>– SLEEPONEXIT = 1 (Refer to the Cortex<sup>®</sup>-M System Control register.)</li> <li>– CPU NVIC interrupts and events cleared.</li> <li>– All CPU EXTI Wakeup sources are cleared.</li> </ul>
<b>Mode exit</b>	If WFI or return from ISR was used for entry: <ul style="list-style-type: none"> <li>– EXTI Interrupt enabled in NVIC: Refer to <a href="#">Table 130: NVIC</a>, for peripheral which are not stopped or powered down.</li> </ul> If WFE was used for entry and SEVONPEND = 0: <ul style="list-style-type: none"> <li>– EXTI event: Refer to <a href="#">Section 20.5.3: EXTI CPU wakeup procedure</a>, for peripheral which are not stopped or powered down.</li> </ul> If WFE was used for entry and SEVONPEND = 1: <ul style="list-style-type: none"> <li>– EXTI Interrupt even when disabled in NVIC: refer to <a href="#">Table 130: NVIC</a> or EXTI event: refer to <a href="#">Section 20.5.3: EXTI CPU wakeup procedure</a>, for peripheral which are not stopped or powered down.</li> </ul>
<b>Wakeup latency</b>	EXTI and RCC wakeup synchronization (see <a href="#">Section 8.4.7: Power-on and wakeup sequences</a> )

### 6.7.7 DStop mode

D1 domain and/or D2 domain enters DStop mode only when the CPU subsystem is in CStop mode and has allocated peripheral in the domain (see [Table 32](#)). In DStop mode the domain bus matrix clock is stopped.

The Flash memory can enter low-power Stop mode when it is enabled through FLPS in PWR\_CR1 register. This allows a trade-off between domain DStop restart time and low power consumption.

**Table 32. DStop mode overview**

Peripheral allocation	CPU	D1 domain	D2 domain	Comment
No peripheral allocated in D2 domain	CRun or CSleep	DRun	DStop	
	CStop	DStop	DStop	
Peripheral allocated in D2 domain	CRun or CSleep	DRun	DRun	CPU subsystem, keep D2 domain active.
	CStop	DStop	DStop	

In DStop mode domain peripherals using the LSI or LSE clock and peripherals having a kernel clock request are still able to operate.

#### Entering DStop mode

The DStop mode is entered according to [Section 6.7.3: Entering low-power modes](#), when at least one PDDS\_Dn bit in [PWR CPU control register \(PWR\\_CPUCR\)](#) for the domain select Stop.

Refer to [Table 33](#) for details on how to enter DStop mode.

If Flash memory programming is ongoing, the DStop mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the DStop mode entry is delayed until the domain bus matrix access is complete.

#### Exiting from DStop mode

The DStop mode is exited according to [Section 6.7.4: Exiting from low-power modes](#).

Refer to [Table 33](#) for more details on how to exit from DStop mode.

When exiting from DStop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling depend on the system mode.

- When the system did not enter Stop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling values are the same as when entering DStop mode.
- When the system has entered Stop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling are reset.

Table 33. DStop mode

DStop mode	Description
Mode entry	<ul style="list-style-type: none"> <li>– The domain CPU subsystem enters CStop.</li> <li>– The CPU subsystem has an allocated peripheral in the D2 domain and enters CStop.</li> <li>– The CPU subsystem deallocated its last peripheral in the D2 domain.</li> <li>– The PDDS_Dn bit for the domain selects Stop mode.</li> </ul>
Mode exit	<ul style="list-style-type: none"> <li>– The domain CPU subsystem exits from CStop mode (see <a href="#">Table 31</a>)</li> <li>– The CPU subsystem has an allocated peripheral in the D2 domain and exits from CStop mode (see <a href="#">Table 31</a>)</li> <li>– The CPU subsystem allocates a first peripheral in the D2 domain.</li> </ul>
Wakeup latency	EXTI and RCC wakeup synchronization (see <a href="#">Section 8.4.7: Power-on and wakeup sequences</a> ).

### 6.7.8 Stop mode

The system D3 domain enters Stop mode only when the CPU subsystem is in CStop mode, the EXTI wakeup sources are inactive and at least one PDDS\_Dn bit in [PWR CPU control register \(PWR\\_CPUCR\)](#) for any domain request Stop. In Stop mode, the system clock including a PLL and the D3 domain bus matrix clocks are stopped. When HSI or CSI is selected, the system oscillator operates according to the HSIKERON and CSIKERON bits in RCC\_CR register. Other system oscillator sources are stopped.

In system D3 domain Stop mode, D1 domain and D2 domain are either in DStop and/or DStandby mode.

In Stop mode, the domain peripherals that use the LSI or LSE clock, and the peripherals that have a kernel clock request to select HSI or CSI as source, are still able to operate.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- Independent watchdog (IWDG)  
The IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset (see [Section 45.3](#) in [Section 45: Independent watchdog \(IWDG\)](#)).
- Real-time clock (RTC)  
This is configured via the RTCEN bit in the [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#).
- Internal RC oscillator (LSI RC)  
This is configured via the LSION bit in the [RCC Clock Control and Status Register \(RCC\\_CSR\)](#).
- External 32.768 kHz oscillator (LSE OSC)  
This is configured via the LSEON bit in the [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#).

- Peripherals capable of running on the LSI or LSE clock.
- Peripherals having a kernel clock request.
- Internal RC oscillators (HSI and CSI)
- This is configured via the HSIKERON and CSIKERON bits in the *RCC Clock Control and Status Register (RCC\_CSR)*.
- The ADC or DAC can also consume power during Stop mode, unless they are disabled before entering this mode. To disable them, the ADON bit in the ADC\_CR2 register and the ENx bit in the DAC\_CR register must both be written to 0.

The selected SVOS4 and SVOS5 levels add an additional startup delay when exiting from system Stop mode (see *Table 34*).

**Table 34. Stop mode operation**

SVOS	LPDS	Stop mode Voltage regulator operation	Wake-up Latency
SVOS3	0	Main	No additional wakeup time.
	1	LP	Voltage Regulator wakeup time from LP mode.
SVOS4 or SVOS5	x	LP	Voltage Regulator wakeup time from LP mode + voltage level wakeup time for SVOS4 or SVOS5 level to VOS3 level

**Entering Stop mode**

The Stop mode is entered according to *Section 6.7.3: Entering low-power modes*, when at least one PDDS\_Dn bit n *PWR CPU control register (PWR\_CPUCR)* for any domain request Stop.

Refer to *Table 35* for details on how to enter Stop mode.

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to a bus matrix is ongoing, the Stop mode entry is delayed until the bus matrix access is finished.

To allow peripherals having a kernel clock request to operate in Stop mode, the system must use SVOS3 level.

**Exiting from Stop mode**

The Stop mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 35* for more details on how to exit from Stop mode.

When exiting from Stop mode, the system clock, D3 domain bus matrix clocks and voltage scaling are reset.

STOPF status flag in *PWR CPU control register (PWR\_CPUCR)* indicates that the system has exited from Stop mode (see *Table 29*).

Table 35. Stop mode

Stop mode	Description
<b>Mode entry</b>	<ul style="list-style-type: none"> <li>– When the CPU is in CStop mode and there is no active EXTI Wakeup source and Run_D3 = 0.</li> <li>– At least one PDDS_Dn bit for any domain select Stop.</li> </ul>
<b>Mode exit</b>	<ul style="list-style-type: none"> <li>– On a EXTI Wakeup.</li> </ul>
<b>Wakeup latency</b>	<ul style="list-style-type: none"> <li>System oscillator startup (when disabled).</li> <li>+ EXTI and RCC wakeup synchronization.</li> <li>+ Voltage Scaling refer to <a href="#">Table 34</a> (see <a href="#">Section 6.6.2: Voltage scaling</a>)</li> </ul>

### I/O states in Stop mode

I/O pin configuration remain unchanged in Stop mode.

### 6.7.9 DStandby mode

Like DStop mode, DStandby mode is based on the CPU subsystem CStop mode. However the domain V<sub>CORE</sub> supply is powered off. A domain enters DStandby mode only when the CPU subsystem is in CStop mode if peripherals are allocated in the domain

A domain enters DStandby mode only when the CPU subsystem is in CStop mode if peripherals are allocated in the domain and the PDDS\_Dn bit in [PWR CPU control register \(PWR\\_CPUCR\)](#) for the domain is configured accordingly. In DStandby mode, the domain is powered down and the domain RAM and register contents are lost.

#### Entering DStandby mode

The DStandby mode is entered according to [Section 6.7.3: Entering low-power modes](#), when the PDDS\_Dn bit in [PWR CPU control register \(PWR\\_CPUCR\)](#) for the Dn domain selects Standby mode.

Refer to [Table 36](#) for details on how to enter DStandby mode.

If Flash memory programming is ongoing, the DStandby mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the DStandby mode entry is delayed until the domain bus matrix access is finished.

*Note:* When the CPU sets the PDDS\_D2 bit to select Standby mode, the D2 domain enters DStandby mode (the CPU has no allocated peripherals in the D2 domain).

#### Exiting from DStandby mode

The DStandby mode is exited according to [Section 6.7.4: Exiting from low-power modes](#).

Refer to [Table 36](#) for more details on how to exit from DStandby mode.

*Note:* When the D2 domain is in DStandby mode and the CPU sets the domain PDDS\_D2 bit to select Stop mode, the D2 domain remains in DStandby mode. The D2 domain will only exit DStandby when the CPU allocates a peripheral in the D2 domain.

When exiting from DStandby mode, the domain CPU and peripherals are reset. However the state of the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling depends on the system mode:

- When the system did not enter Stop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling are the same as when entering DStandby mode.
- When the system has entered Stop or Standby mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling are reset.

When the D2 domain exits from DStandby mode due to the CPU subsystem (i.e when allocating a first peripheral or when peripherals are allocated in the D2 domain and the CPU subsystem exits from CStop mode), the CPU shall verify that the domain has exited from DStandby mode. To ensure correct operation, it is recommended to follow the sequence below:

1. First check that the domain bus matrix clock is available. The domain bus matrix clock state can be checked in RCC\_CR register:
  - When RCC DnCKRDY = 0, the domain bus matrix clock is stalled.
  - If RCC DnCKRDY = 1, the domain bus matrix clock is enabled.
2. Then **wait that** the domain has exited from DStandby mode. To do this, check the SBF\_Dn flag in *PWR CPU control register (PWR\_CPUCR)*. The domain is powered and can be accessed only when SBF\_Dn is cleared. Below an example of code:

```

Loop
write PWR SBF_Dn = 0 ; try to clear bit.
read PWR SBF_Dn
While 1 ==> loop
    
```

**Table 36. DStandby mode**

DStandby mode	Description
<b>Mode entry</b>	– The domain CPU subsystem enters CStop. – The CPU subsystem has an allocated peripheral in D2 domain and enters CStop. – The CPU subsystem deallocated its last peripheral in the D2 domain. – The PDDS_Dn bits for the domain select Standby mode. – All WKUPF bits in Power Control/Status register (PWR_WKUPFR) are cleared.
<b>Mode exit</b>	– The CPU subsystem exits from CStop mode (see <a href="#">Table 31</a> ) – The CPU subsystem has an allocated peripheral in the D2 domain and exits from CStop mode (see <a href="#">Table 31</a> ) – The CPU subsystem allocates a first peripheral in the D2 domain.
<b>Wakeup latency</b>	EXTI and RCC wakeup synchronization. + Domain power up and reset. (see <a href="#">Section 8.4.7: Power-on and wakeup sequences</a> )

### 6.7.10 Standby mode

The Standby mode allows achieving the lowest power consumption. Like Stop mode, it is based on CPU subsystem CStop mode. However the  $V_{\text{CORE}}$  supply regulator is powered off.

The system D3 domain enters Standby mode only when the D1 and D2 domain are in DStandby. When the system D3 domain enters Standby mode, the voltage regulator is disabled. The complete  $V_{\text{CORE}}$  domain is consequently powered off. The PLLs, HSI oscillator, CSI oscillator, HSI48 and the HSE oscillator are also switched off. SRAM and register contents are lost except for backup domain registers (RTC registers, RTC backup register and backup RAM), and Standby circuitry (see [Section 6.4.4: Backup domain](#)).

In system Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG)  
The IWDG is started by programming its Key register or by hardware option. Once started, it cannot be stopped except by a reset (see [Section 45.3 in Section 45: Independent watchdog \(IWDG\)](#)).
- Real-time clock (RTC)  
This is configured via the RTCEN bit in the backup domain control register (RCC\_BDCR).
- Internal RC oscillator (LSI RC)  
This is configured by the LSION bit in the Control/status register (RCC\_CSR).
- External 32.768 kHz oscillator (LSE OSC)  
This is configured by the LSEON bit in the backup domain control register (RCC\_BDCR).

#### Entering Standby mode

The Standby mode is entered according to [Section 6.7.3: Entering low-power modes](#), when all PDDS\_Dn bits in [PWR CPU control register \(PWR\\_CPUCR\)](#) for all domains request Standby.

Refer to [Table 38](#) for more details on how to enter to Standby mode.

#### Exiting from Standby mode

The Standby mode is exited according to [Section 6.7.4: Exiting from low-power modes](#).

Refer to [Table 38](#) for more details on how to exit from Standby mode.

The system exits from Standby mode when an external Reset (NRST pin), an IWDG Reset, a WKUP pin event, a RTC alarm, a tamper event, or a time stamp event is detected. All registers are reset after waking up from Standby except for power control and status registers ([PWR control register 2 \(PWR\\_CR2\)](#), [PWR control register 3 \(PWR\\_CR3\)](#)), SBF bit in [PWR CPU control register \(PWR\\_CPUCR\)](#), [PWR wakeup flag register \(PWR\\_WKUPFR\)](#), and [PWR wakeup enable and polarity register \(PWR\\_WKUPEFR\)](#).

After waking up from Standby mode, the program execution restarts in the same way as after a system reset (boot option sampling, boot vector reset fetched, etc.). The SBF status flags in [PWR CPU control register \(PWR\\_CPUCR\)](#) registers indicate from which mode the system has exited (see [Table 37](#)).

**Table 37. Standby and Stop flags**

SBF_D2	SBF_D1	SBF	STOPF	Description
0	1	0	0	D1 domain exits from DStandby while system stayed in Run
0	1	0	1	D1 domain exits from DStandby, while system has been in or exits from Stop
1	0	0	0	D2 domain exits from DStandby while system stayed in Run
1	0	0	1	D2 domain exits from DStandby while system has been in or exits from Stop
1	1	0	0	D1 and D2 domain exit from DStandby while the system remains in Run mode
1	1	0	1	D1 and D2 domain exit from DStandby while the system is in Stop mode or is exiting this mode.
0	0	0	1	System has been in or exits from Stop
0 <sup>(1)</sup>	0 <sup>(1)</sup>	1	0	System exits from Standby

1. When exiting from Standby the SBF\_D1 and SBF\_D2 reflect the reset value

**Table 38. Standby mode**

Standby mode	Description
<b>Mode entry</b>	<ul style="list-style-type: none"> <li>– The CPU subsystem is in CStop mode, and there is no active EXTI Wakeup source and RUN_D3 = 0.</li> <li>– All PDDS_Dn bits for all domains select Standby.</li> <li>– All WKUPF bits in Power Control/Status register (PWR_WKUPFR) are cleared.</li> </ul>
<b>Mode exit</b>	<ul style="list-style-type: none"> <li>– WKUP pins rising or falling edge, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time stamp event, external reset in NRST pin, IWDG reset.</li> </ul>
<b>Wakeup latency</b>	System reset phase (see <a href="#">Section 8.4.2: System reset</a> )

**I/O states in Standby mode**

In Standby mode, all I/O pins are high impedance without pull, except for:

- Reset pad (still available)
- RTC\_AF1 pin if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins (if enabled). The WKUP pin pull configuration can be defined through WKUPPUPD register bits in [PWR wakeup enable and polarity register \(PWR\\_WKUPPEPR\)](#).

## 6.8 PWR register description

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

### 6.8.1 PWR control register 1 (PWR\_CR1)

Address offset: 0x000

Reset value: 0xF000 C000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	ALS		AVDEN
													r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SVOS		Res	Res	Res	Res	FLPS	DBP	PLS			PVDE	Res	Res	Res	LPDS
r/w	r/w					r/w	r/w	r/w	r/w	r/w	r/w				r/w

Bits 31:19 Reserved, must be kept at reset value

Bits 18:17 **ALS**: Analog voltage detector level selection

These bits select the voltage threshold detected by the AVD.

00: 1.7 V

01: 2.1 V

10: 2.5 V

11: 2.8 V

Bit 16 **AVDEN**: Peripheral voltage monitor on V<sub>DDA</sub> enable

0: Peripheral voltage monitor on V<sub>DDA</sub> disabled.

1: Peripheral voltage monitor on V<sub>DDA</sub> enabled

Bits 15:14 **SVOS**: System Stop mode voltage scaling selection

These bits control the V<sub>CORE</sub> voltage level in system Stop mode, to obtain the best trade-off between power consumption and performance.

00: Reserved

01: SVOS5 Scale 5

10: SVOS4 Scale 4

11: SVOS3 Scale 3 (default)

Bits 13:10 Reserved, must be kept at reset value

Bit 9 **FLPS**: Flash low-power mode in DStop mode

This bit allows to obtain the best trade-off between low-power consumption and restart time when exiting from DStop mode.

When it is set, the Flash memory enters low-power mode when D1 domain is in DStop mode.

0: Flash memory remains in normal mode when D1 domain enters DStop (quick restart time).

1: Flash memory enters low-power mode when D1 domain enters DStop mode (low-power consumption).

Bit 8 **DBP**: Disable backup domain write protection

In reset state, the RCC\_BDCR register, the RTC registers (including the backup registers), BREN and MOEN bits in PWR\_CR2 register, are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Access to RTC, RTC Backup registers and backup SRAM disabled

1: Access to RTC, RTC Backup registers and backup SRAM enabled

Bits 7:5 **PLS**: Programmable voltage detector level selection

These bits select the voltage threshold detected by the PVD.

000: 1.95 V

001: 2.1 V

010: 2.25 V

011: 2.4 V

100: 2.55 V

101: 2.7 V

110: 2.85 V

111: External voltage level on PVD\_IN pin, compared to internal  $V_{REFINT}$  level.

*Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.*

Bit 4 **PVDE**: Programmable voltage detector enable

0: Programmable voltage detector disabled.

1: Programmable voltage detector enabled

Bits 3:1 Reserved, must be kept at reset value

Bit 0 **LPDS**: Low-power Deepsleep with SVOS3 (SVOS4 and SVOS5 always use low-power, regardless of the setting of this bit)

0: Voltage regulator in Main mode (MR) when SVOS3 is selected for Stop mode

1: Voltage regulator in Low-power mode (LPR) when SVOS3 is selected for Stop mode

### 6.8.2 PWR control status register 1 (PWR\_CSR1)

Address offset: 0x004

Reset value: 0x0000 4000.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AVDO
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACTVOS		ACTVOS RDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	Res.	Res.	Res.
r		r									r				

Bits 31:17 Reserved, must be kept at reset value

Bit 16 **AVDO**: Analog voltage detector output on  $V_{DDA}$

This bit is set and cleared by hardware. It is valid only if AVD on  $V_{DDA}$  is enabled by the AVDEN bit.

0:  $V_{DDA}$  is equal or higher than the AVD threshold selected with the ALS[2:0] bits.

1:  $V_{DDA}$  is lower than the AVD threshold selected with the ALS[2:0] bits

*Note: Since the AVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the AVDEN bit is set.*

Bits 15:14 **ACTVOS**: VOS currently applied for  $V_{CORE}$  voltage scaling selection.

These bits reflect the last VOS value applied to the voltage regulator.

Bit 13 **ACTVOSRDY**: Voltage levels ready bit for currently used VOS

This bit is set to 1 by hardware when the voltage regulator is disabled and Bypass mode is selected in PWR control register 3 (PWR\_CR3).

0: Voltage level invalid, above or below current VOS selected level.

1: Voltage level valid, at current VOS selected level.

Bits 12:5 Reserved, must be kept at reset value

Bit 4 **PVDO**: Programmable voltage detect output

This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.

0:  $V_{DD}$  or PVD\_IN voltage is equal or higher than the PVD threshold selected through the PLS[2:0] bits.

1:  $V_{DD}$  or PVD\_IN voltage is lower than the PVD threshold selected through the PLS[2:0] bits.

*Note: since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.*

Bits 3:0 Reserved, must be kept at reset value

### 6.8.3 PWR control register 2 (PWR\_CR2)

Address offset: 0x008

Reset value: 0x0000 0000

This register is not reset by wakeup from Standby mode, RESET signal and V<sub>DD</sub> POR. It is only reset by V<sub>SW</sub> POR and VSWRST reset.

This register shall not be accessed when VSWRST bit in RCC\_BDCR register resets the V<sub>SW</sub> domain.

After reset, PWR\_CR2 register is write-protected. Prior to modifying its content, the DBP bit in PWR\_CR1 register must be set to disable the write protection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEMPH	TEMPL	VBATH	VBATL	Res.	Res.	Res.	BRRDY
								r	r	r	r				r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	Res.	Res.	Res.	BREN
											rw				rw

Bits 31:24 Reserved, must be kept at reset value

Bit 23 **TEMPH**: Temperature level monitoring versus high threshold  
 0: Temperature below high threshold level.  
 1: Temperature equal or above high threshold level.

Bit 22 **TEMPL**: Temperature level monitoring versus low threshold  
 0: Temperature above low threshold level.  
 1: Temperature equal or below low threshold level.

Bit 21 **VBATH**: V<sub>BAT</sub> level monitoring versus high threshold  
 0: V<sub>BAT</sub> level below high threshold level.  
 1: V<sub>BAT</sub> level equal or above high threshold level.

Bit 20 **VBATL**: V<sub>BAT</sub> level monitoring versus low threshold  
 0: V<sub>BAT</sub> level above low threshold level.  
 1: V<sub>BAT</sub> level equal or below low threshold level.

Bits 19:17 Reserved, must be kept at reset value

Bit 16 **BRRDY**: Backup regulator ready  
 This bit is set by hardware to indicate that the Backup regulator is ready.  
 0: Backup regulator not ready.  
 1: Backup regulator ready.

Bits 15:5 Reserved, must be kept at reset value

Bit 4 **MONEN**:  $V_{BAT}$  and temperature monitoring enable  
 When set, the  $V_{BAT}$  supply and temperature monitoring is enabled.  
 0:  $V_{BAT}$  and temperature monitoring disabled.  
 1:  $V_{BAT}$  and temperature monitoring enabled.

Bits 3:1 Reserved, must be kept at reset value

Bit 0 **BREN**: Backup regulator enable  
 When set, the Backup regulator (used to maintain the backup RAM content in Standby and  $V_{BAT}$  modes) is enabled.  
 If BREN is reset, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However, its content will be lost in Standby and  $V_{BAT}$  modes.  
 If BREN is set, the application must wait till the Backup Regulator Ready flag (BRRDY) is set to indicate that the data written into the SRAM will be maintained in Standby and  $V_{BAT}$  modes.  
 0: Backup regulator disabled.  
 1: Backup regulator enabled.

### 6.8.4 PWR control register 3 (PWR\_CR3)

Address offset: 0x00C

Reset value: 0x0000 0006 (reset only by POR only, not reset by wakeup from Standby mode and RESET pad).

The lower byte of this register is written once after POR and shall be written before changing VOS level or ck\_sys clock frequency. No limitation applies to the upper bytes.

Programming data corresponding to an invalid combination of LDOEN and BYPASS bits (see [Table 26](#)) will be ignored: data will not be written, the written-once mechanism will lock the register and any further write access will be ignored. The default supply configuration will be kept and the ACTVOSRDY bit in [PWR control status register 1 \(PWR\\_CSR1\)](#) will go on indicating invalid voltage levels. The system shall be power cycled before writing a new value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	USB33RDY	USBREGEN	USB33DEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:27 Reserved, must be kept at reset value

Bit 26 **USB33RDY**: USB supply ready.  
 0: USB33 supply not ready.  
 1: USB33 supply ready.

- Bit 25 **USBREGEN**: USB regulator enable.  
 0: USB regulator disabled.  
 1: USB regulator enabled.
- Bit 24 **USB33DEN**: V<sub>DD33USB</sub> voltage level detector enable.  
 0: V<sub>DD33USB</sub> voltage level detector disabled.  
 1: V<sub>DD33USB</sub> voltage level detector enabled.
- Bits 23:10 Reserved, must be kept at reset value
- Bit 9 **VBRS**: V<sub>BAT</sub> charging resistor selection  
 0: Charge V<sub>BAT</sub> through a 5 kΩ resistor.  
 1: Charge V<sub>BAT</sub> through a 1.5 kΩ resistor.
- Bit 8 **VBE**: V<sub>BAT</sub> charging enable  
 0: V<sub>BAT</sub> battery charging disabled.  
 1: V<sub>BAT</sub> battery charging enabled.
- Bits 7:3 Reserved, must be kept at reset value
- Bit 2 **SCUEN**: Supply configuration update enable  
 This bit is read-only:  
 0: Supply configuration update locked.  
 1: Single write enabled to Supply configuration (LDOEN and BYPASS)
- Bit 1 **LDOEN**: Low drop-out regulator enable  
 0: Low drop-out regulator disabled.  
 1: Low drop-out regulator enabled (default)
- Bit 0 **BYPASS**: Power management unit bypass  
 0: Power management unit normal operation.  
 1: Power management unit bypassed, voltage monitoring still active.

### 6.8.5 PWR CPU control register (PWR\_CPUCR)

This register allows controlling CPU power.

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw		rw	r	r	r	r			rw	rw	rw

- Bits 31:12 Reserved, must be kept at reset value
- Bit 11 **RUN\_D3**: Keep system D3 domain in Run mode regardless of the CPU subsystem modes  
 0: D3 domain follows CPU subsystem modes.  
 1: D3 domain remains in Run mode regardless of CPU subsystem modes.
- Bit 10 Reserved, must be kept at reset value

- Bit 9 **CSSF**: Clear Standby and Stop flags (always read as 0)  
This bit is cleared to 0 by hardware.  
0: No effect.  
1: STOPF, SBF, SBF\_D1, and SBF\_D2 flags are cleared.
- Bit 8 **SBF\_D2**: D2 domain DStandby flag  
This bit is set by hardware and cleared by any system reset or by setting the CSSF bit. Once set, this bit can be cleared only when the D2 domain is no longer in DStandby mode.  
0: D2 domain has not been in DStandby mode  
1: D2 domain has been in DStandby mode.
- Bit 7 **SBF\_D1**: D1 domain DStandby flag  
This bit is set by hardware and cleared by any system reset or by setting the CSSF bit. Once set, this bit can be cleared only when the D1 domain is no longer in DStandby mode.  
0: D1 domain has not been in DStandby mode  
1: D1 domain has been in DStandby mode.
- Bit 6 **SBF**: System Standby flag  
This bit is set by hardware and cleared only by a POR (Power-on Reset) or by setting the CSSF bit  
0: System has not been in Standby mode  
1: System has been in Standby mode
- Bit 5 **STOPF**: STOP flag  
This bit is set by hardware and cleared only by any reset or by setting the CSSF bit.  
0: System has not been in Stop mode  
1: System has been in Stop mode
- Bits 4:3 Reserved, must be kept at reset value
- Bit 2 **PDDS\_D3**: System D3 domain Power Down Deepsleep.  
This bit allows defining the Deepsleep mode for System D3 domain.  
0: Keep Stop mode when D3 domain enters Deepsleep.  
1: Allow Standby mode when D3 domain enters Deepsleep.
- Bit 1 **PDDS\_D2**: D2 domain Power Down Deepsleep.  
This bit allows defining the Deepsleep mode for D2 domain.  
0: Keep DStop mode when D2 domain enters Deepsleep.  
1: Allow DStandby mode when D2 domain enters Deepsleep.
- Bit 0 **PDDS\_D1**: D1 domain Power Down Deepsleep selection.  
This bit allows defining the Deepsleep mode for D1 domain.  
0: Keep DStop mode when D1 domain enters Deepsleep.  
1: Allow DStandby mode when D1 domain enters Deepsleep.

### 6.8.6 PWR D3 domain control register (PWR\_D3CR)

This register allows controlling D3 domain power.

Address offset: 0x018

Reset value: 0x0000 4000 (Following reset VOSRDY will be read 1 by software).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VOS	VOSRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	r														

Bits 31:16 Reserved, must be kept at reset value

Bits 15:14 **VOS**: Voltage scaling selection according to performance

These bits control the  $V_{CORE}$  voltage level and allow to obtains the best trade-off between power consumption and performance:

- When increasing the performance, the voltage scaling shall be changed before increasing the system frequency.
- When decreasing performance, the system frequency shall first be decreased before changing the voltage scaling.

00: Reserved (Scale 3 selected).

01: Scale 3 (default)

10: Scale 2

11: Scale 1

Bit 13 **VOSRDY**: VOS Ready bit for  $V_{CORE}$  voltage scaling output selection.

This bit is set to 1 by hardware when Bypass mode is selected in PWR control register 3 (PWR\_CR3).

0: Not ready, voltage level below VOS selected level.

1: Ready, voltage level at or above VOS selected level.

Bits 12:0 Reserved, must be kept at reset value

### 6.8.7 PWR wakeup clear register (PWR\_WKUPCR)

Address offset: 0x020

Reset value: 0x0000 0000 (reset only by system reset, not reset by wakeup from Standby mode)

5 wait states are required when writing this register (when clearing a WKUPF bit in PWR\_WKUPFR, the AHB write access will complete after the WKUPF has been cleared).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

											rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, always read as 0.

Bits 5:0 **WKUPCn+1**: Clear Wakeup pin flag for WKUPn+1.

These bits are always read as 0.

0: No effect

1: Writing 1 clears the WKUPF<sub>n+1</sub> Wakeup pin flag (bit is cleared to 0 by hardware)

### 6.8.8 PWR wakeup flag register (PWR\_WKUPFR)

Address offset: 0x024

Reset value: 0x0000 0000 (reset only by system reset, not reset by wakeup from Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPF6	WKUPF5	WKUPF4	WKUPF3	WKUPF2	WKUPF1
											r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value

Bits 5:0 **WKUPn+1**: Wakeup pin WKUPn+1 flag.

This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC<sub>n+1</sub> bit in the [PWR wakeup clear register \(PWR\\_WKUPCR\)](#).

0: No wakeup event occurred

1: A wakeup event was received from WKUPn+1 pin

### 6.8.9 PWR wakeup enable and polarity register (PWR\_WKUPEPR)

Address offset: 0x028

Reset value: 0x0000 0000 (reset only by system reset, not reset by wakeup from Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	WKUPPUPD6		WKUPPUPD5		WKUPPUPD4		WKUPPUPD3		WKUPPUPD2		WKUPPUPD1	
				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	WKUPP6	WKUPP5	WKUPP4	WKUPP3	WKUPP2	WKUPP1	Res.	Res.	WKUPEN6	WKUPEN5	WKUPEN4	WKUPEN3	WKUPEN2	WKUPEN1
		r/w	r/w	r/w	r/w	r/w	r/w			r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:28 Reserved, must be kept at reset value

Bits 27:16 **WKUPPUPD[truncate(n/2)-7]**: Wakeup pin pull configuration for WKUP(truncate(n/2)-7)

These bits define the I/O pad pull configuration used when WKUPEN(truncate(n/2)-7) = 1. The associated GPIO port pull configuration shall be set to the same value or to '00'.

The Wakeup pin pull configuration is kept in Standby mode.

00: No pull-up

01: Pull-up

10: Pull-down

11: Reserved

Bits 15:14 Reserved, must be kept at reset value

Bits 13:8 **WKUPPn-7**: Wakeup pin polarity bit for WKUPn-7

These bits define the polarity used for event detection on WKUPn-7 external wakeup pin.

0: Detection on high level (rising edge)

1: Detection on low level (falling edge)

Bits 7:6 Reserved, must be kept at reset value

Bits 5:0 **WKUPENn+1**: Enable Wakeup Pin WKUPn+1

Each bit is set and cleared by software.

0: An event on WKUPn+1 pin does not wake up the system from Standby mode.

1: A rising or falling edge on WKUPn+1 pin wakes up the system from Standby mode.

*Note: An additional wakeup event is detected if WKUPn+1 pin is enabled (by setting the WKUPENn+1 bit) when WKUPn+1 pin level is already high when WKUPPn+1 selects rising edge, or low when WKUPPn+1 selects falling edge.*

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 7 Low-power D3 domain

This section describes, through an example, how to use the D3 domain to implement low-power applications.

### 7.1 Introduction

The first part of the description explains how the EXTI, RCC and PWR blocks interact with each other and with the other system blocks. A detailed explanation on how the DMAMUX2 can be used to free the CPU is also provided.

The second part explains how to use the Autonomous mode to perform simple data transfers through an example of LINUART1 transmission.

Register programming is detailed only for the blocks related to the Autonomous mode.

### 7.2 EXTI, RCC and PWR interconnections

[Figure 30](#) shows the main EXTI, RCC and PWR interconnections.

Figure 30. EXTI, RCC and PWR interconnections

## 7.2.1 Interrupts and wakeup

Three kinds of signals are exchanged between the peripherals. They can be used to wake up the system from Stop mode:

- **Wakeup events** (or asynchronous interrupts)  
Some peripherals can generate interrupt events, even if their bus interface clock is not present. These interrupt events are called wakeup events (or asynchronous interrupts).  
Example: `i2c1_wkup`, `usart1_wkup` and `lptim1_wkup`.
- **Signals**  
Some peripherals generate a pulse instead of an interrupt signal. These pulses are called signals.  
Examples: `lptim2_out` and `lptim3_out`.
- **Interrupts**  
Contrary to signals, the interrupts should be cleared by a CPU or any other bus master, either by clearing the corresponding event bit in the peripheral register or by updating the FIFO interrupt level.  
All the interrupts associated to system peripherals are directly connected to the NVIC, except for the peripherals which are able to wake up the system from Stop mode or the CPU from CStop. In this latter case, the interrupts, signals or wakeup events are connected to the NVIC via the EXTI.  
Example: `spi1_it`, `tim1_brk_it` and `tim1_upd_it`.

The interrupt and wakeup sources that require to be cleared in the peripheral itself are connected to EXTI Direct Event inputs. The EXTI does not manage any CPU status pending bit.

The peripherals signals are connected to EXTI Configurable Event inputs. These EXTI inputs provide a CPU status pending bit which needs to be cleared by the application.

## 7.2.2 Block interactions

### Interaction between EXTI and PWR blocks

The EXTI delivers wakeup requests signals (`exti_c_wkup`, `exti_d3_wkup`) to the PWR controller. These signals are activated according to the state of the interrupts, signals or wakeup events connected to the EXTI. These wakeup requests are used by the PWR controller to supply the domain who needs to handle the activated wakeup event generated by the peripherals.

### Interaction between PWR and RCC blocks

The PWR block controls the  $V_{DD11}$  supply according to the system operating mode (CRun, CSleep or CStop). The PWR block also controls the power switches (ePODs) that delivers  $V_{DD11}$  supply to D1 and D2 domains.

The RCC block controls the clock generation in accordance with the system operating mode. It is also responsible for reset generation.

To synchronize the system mode transitions, the RCC block is tightly coupled with the PWR controller:

- The RCC informs the PWR controller when peripherals located in Dx domain are allocated by the CPU (**c\_per\_alloc\_d2**, **c\_per\_alloc\_d1**).
- The RCC also warns the PWR block when a domain clock is activated/deactivated. These signals are used in case of domain transition from DRun to DStop or DStandby. In this case, the PWR controller waits until the domain clock has been gated, before switching down this domain.
- Similarly, the PWR controller informs the RCC about the  $V_{DD11}$  supply status of each domain (**pwr\_d[1:3]\_wkup**). This information is used by the RCC when a domain transition from DStop or DStandby to DRun occurs.

### Interaction between EXTI and D3 domain

All the wakeup event inputs received by the EXTI from the peripherals located in D3 domain are forwarded back to the D3 domain after system clock re-synchronization. These events are used by the D3 domain to perform autonomous operations without activating the CPU.

The EXTI **D3\_PenClear[3:0]** inputs received from the D3 domain are used to acknowledge the ongoing wakeup requests generated by peripherals located in the D3 domain. The **D3\_PenClear[3:0]** inputs allow switching the system D3 domain from Run to Stop mode.

### 7.2.3 Role of D3 domain DMAMUX2

The DMAMUX2 implemented in the D3 domain allows chaining BDMA transfers. BDMA requests are synchronized thanks to trigger events (**dmamux2\_evtx**) which can be generated when the expected amount of data has been transferred.

These events can also trigger DMAMUX2 request generators (REQ\_GEN[3:0]), and thus chain several BDMA transfers. In fact REQ\_GEN[3:0] can be triggered indirectly by all the wakeup events generated by all D3 domain peripherals.

Like LPTIM5 and LPTIM4 outputs, dmamux2\_evt7 and dmamux2\_evt6 events are connected to the EXTI. They can be used to switch the D3 domain from DRun to DStop mode when the task requested by the wakeup event is complete.

## 7.3 Low-power application example based on LPUART1 transmission

This section illustrates, through an example, the benefit of the D3 domain usage on power consumption. To help the user program the device, only the key register settings are given herein.

Refer to [Section 8: Reset and Clock Control \(RCC\)](#) and [Section 6: Power control \(PWR\)](#) for additional details.

### 7.3.1 Memory retention

The D3 domain features 64 Kbytes of SRAM (SRAM4), which can be used to retain data while the D1 and D2 domains enter DStandby mode.

This feature can be used in several use-cases:

- to retain the application code in order to recover properly from DStandby
- to retain the data from/to a sensor when the CPU enters CStop with D1 or D2 domain in DStandby) between two consecutive operations.

*Note:* SRAM4 remains available as long as the system is not in Standby mode.

*If the system is in Standby mode, it is still possible to use the BKUP\_SRAM. However, its size is limited to 4 Kbytes.*

### 7.3.2 Memory-to-peripheral transfer using LPUART1 interface

#### Example description

[Figure 31](#) shows the proposed implementation. At a regular time interval given by LPTIM4, the CPU wakes up from CStop mode (which domain is in DStandby). When the CPU is in Run mode, it prepares the data to be transmitted via LPUART1, transfers them to SRAM4, and goes back to CStop. The D3 domain is configured to perform data transfers via LPUART1 and go back to Stop mode when the transfer is complete.

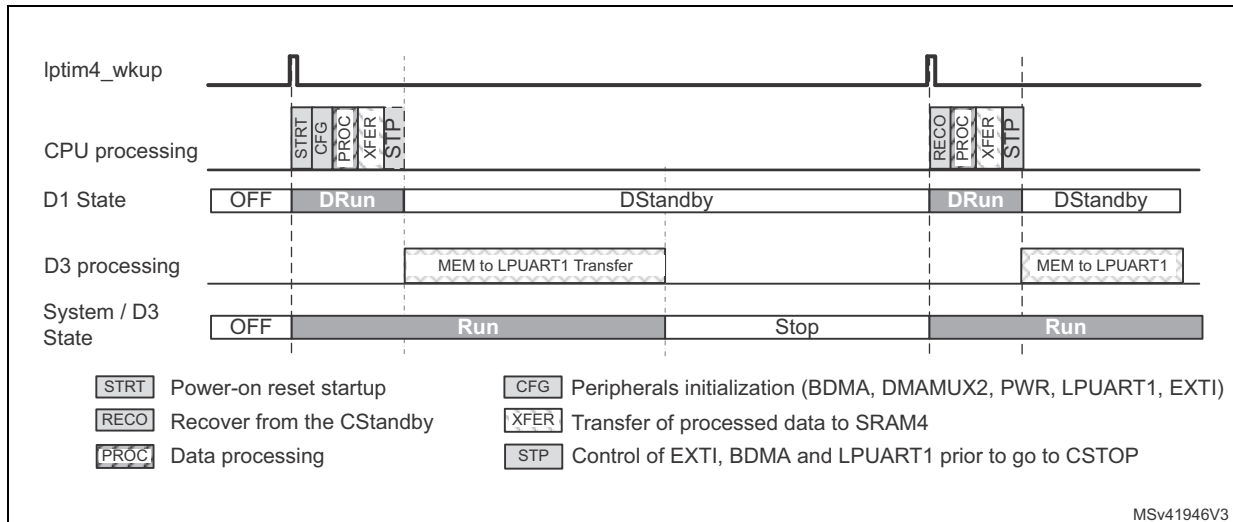

The LPTIM4 interface is used to wake up the system from Standby at regular time intervals. the CPU must then perform the following operations:

1. Recover the application from the system Standby mode (RECO).
2. Process the new data to be sent via LPUART1 (PROC).
3. Transfer the data into SRAM4 (XFER).
4. Configure the DMAMUX2, the BDMA, the LPUART1, and the RCC (CFG).
5. Configure the EXTI (CFG).
6. Configure the PWR block to allow D1 domain to go to DStandby (STP).
7. Set the CPU to Stop mode.

The D3 domain executes the following tasks in Autonomous mode:

1. Transfer the data from SRAM4 to LPUART1, using BDMA.
2. When the LPUART1 interface indicates that the last byte has been transferred, the D3 domain is switched to Stop mode.

**Figure 31. Timing diagram of SRAM4-to-LPUART1 transfer with BDMA and D3 domain in Autonomous mode**

**Note:** In the example described in this section, the D3 domain cannot be kept in Run mode when D1 and D2 domains are in DStop/DStandby by using the RUN\_D3 bit of PWR\_CPUCR register. RUN\_D3 will force the D3 domain to Run mode, but it will not be able to go back to Stop on its own.

If the application needs to toggle the D3 domain between Stop and Run modes, then the Run mode must be triggered by a wakeup event so that the D3 domain can clear this event is needed.

### RCC programming

In this example, the CPU sub-system also includes the peripherals of D3 domain that are used for the data transfer, that is BDMA, DMAMUX2, LPUART1 and LPTIM4. These peripherals must be programmed in Autonomous mode, in order to operate even when the CPU is in CSTOP mode.

LPUART1 can use its own APB clock as kernel clock. Since the system will not enter Stop mode before LPUART1 has completed data transfer, PLLx can be used to provide clocks to the peripherals.

### PWR programming

In this example, the PWR block must be programmed in order to:

- Prevent system D3 domain to enter Standby mode when the data transfer is complete.
- Allow the D1 domain to enter DStandby.
- Define the working voltage according to system modes.

**Note:** D3 domain could enter Standby as well, but in this case the LPTIM4 could not be used to wake up the system and the AWU should be used instead. In addition, everything must be reprogrammed when the system wakes up.

## EXTI programming

The EXTI block must be configured to provide the following services:

- Keep D3 domain running when D1 domain is in DStandby. This will be done by a software event.
- Set the device to Stop mode when the data transfer via LPUART1 is complete.
- Wake up the product from Stop when LPTIM4 time interval has elapsed.

The EXTI block is configured once before performing the first data transfer. For incoming data transfers, the programmed configuration remains unchanged; only some events need to be triggered or acknowledged.

*Note:* The CPU uses the event input number 0 to generate a software event. LPTIM4 wakeup signal is connected to event input number 52 (direct event input).

All other event inputs must be disabled: `EXTI_RTSTRx_TRy = '0'` and `EXTI_FTSTRx_TRy = '0'`.

To generate a wakeup event for D3 domain, the CPU must write SWIER0 bit of EXTI\_SWIER1 to '1'. The GPIO connected to this event input must not toggle in order to avoid spurious wakeup. To prevent the GPIO to disturb, the following sequence can be done:

## BDMA and DMAMUX2 programming

Two BDMA channels are required to execute data transfers via LPUART1.

- A BDMA channel, such as channel 0, is used to transfer data from SRAM4 to LPUART1, using the TXE flag.
- The second BDMA channel role is to switch the D3 domain to Stop mode. For that purpose, DMAMUX2 request generator channel 0 (REQ\_GEN0) and DMAMUX2 channel 7 synchronization block (SYNC7) are used in conjunction with BDMA channel 7.

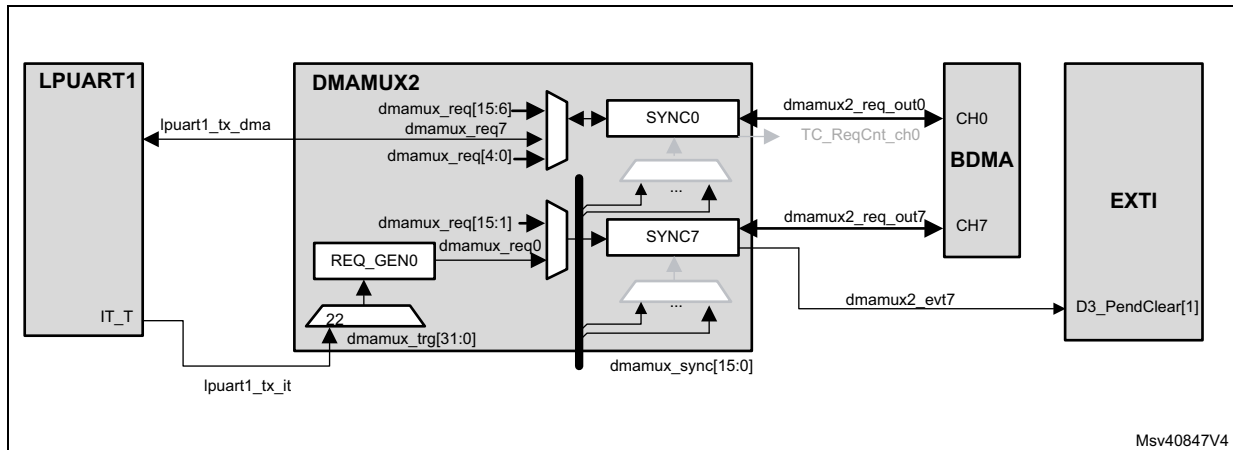

BDMA channel 0 does not use DMAMUX2 trigger capabilities. Refer to [Table 41](#) for initialization details.

BDMA channel 7 uses REQ\_GEN0 to generate BDMA requests. The generation of BDMA requests is triggered by the LPUART1 transmit interrupt (`lpuart1_tx_it`). The LPUART1 interface generates `lpuart1_tx_it` interrupt when the transmit complete event is detected. The BDMA then clears the pending interrupt by performing a write operation to the LPUART1.

The SYNC7 block is programmed in Free-running mode. It generates a pulse on its `dmamux2_evt7` output when the BDMA request generated by the REQ\_GEN0 is complete. `dmamux2_evt7` signal is used by the EXTI to switch back the D3 domain to Stop mode.

[Figure 40](#) shows the active signal paths via DMAMUX2. The grayed blocks represent the unused paths.

**Table 40. BDMA and DMAMUX2 interconnection**

Msv40847V4

Table 41 explain how to program BDMA and DMAMUX2 key functions. The way errors are handled is not described.

**Table 41. BDMA and DMAMUX2 initialization sequence (DMAMUX2\_INIT)**

Peripherals	Register content	Related actions
DMAMUX2 SYNC0	DMAREQ_ID of DMAMUX2_C0CR = '7' SE of DMAMUX2_C0CR = '0' EGE of DMAMUX2_C0CR = '0' NBREQ of DMAMUX2_C0CR = '0'	Selects LPUART_TX BDMA request. Disables block synchronization. No event generation. Generates an event every BDMA transfer (free running mode).
DMAMUX2 SYNC7	DMAREQ_ID of DMAMUX2_C7CR = '0' SE of DMAMUX2_C7CR = '0' EGE of DMAMUX2_C7CR = '1' NBREQ of DMAMUX2_C7CR = '0'	Selects of REQ_GEN0 as BDMA request. Disables block synchronization. Enables event generation. Generates an event every BDMA transfer (free running mode).
DMAMUX2 REQ_GEN0	SIG_ID of DMAMUX2_RG0CR = '0d24' GPOL of DMAMUX2_RG0CR = '0b01' GNBREQ of DMAMUX2_RG0CR = '0' GE of DMAMUX2_RG0CR = '1'	Selects LPUART TX interrupt as trigger. Trigger on rising edge of the event. Generates only one BDMA request. Enables generator.

**Table 41. BDMA and DMAMUX2 initialization sequence (DMAMUX2\_INIT) (continued)**

Peripherals	Register content	Related actions
BDMA - CH0	NDT bits of BDMA_CNDTR0 = DatNber PA of BDMA_CPAR0 = &LPUART1_TDR MA of BDMA_CMAR0 = &DatBuff DIR of BDMA_CCR0 = '1' CIRC of BDMA_CCR0 = '0' PINC of BDMA_CCR0 = '0' MINC of BDMA_CCR0 = '1' PSIZE of BDMA_CCR0 = '0' MSIZE of BDMA_CCR0 = '1' MEM2MEM of BDMA_CCR0 = '0'	Number of data to transfer. Circular mode disabled. Peripheral increment disabled. Memory increment disabled. Peripheral size = 32 bits. Memory size = 32 bits. Memory to memory disabled.

**LPTIM4 programming**

When LPTIM4 wakeup event occurs, the CPU reboots and D3 domain mode is also set to Run mode.

An interrupt issued by LPTIM4 is pending on the CPU NVIC. LPTIM4 interrupt handler must acknowledge this LPTIM4 interrupt by writing ARRMCF bit in LPTIM4\_ICR register to '1' (LPTIM4\_Ack).

**LPUART programming**

In the use-case described herein, the capability of the LPUART1 to request the kernel clock according to some events is not used.

LPUART1 is programmed so that it generates a BDMA request when its TX-FIFO is not full.

LPUART1 also generates an interrupt when the TX-FIFO and its transmit shift register are empty. This interrupt is used to switch the D3 domain to Stop mode.

[Table 42](#) gives the key settings concerning the handling of Stop mode for LPUART1.

**Table 42. LPUART1 Initial programming (LPUART1\_INIT)**

Register content	Related actions
FIFOEN of LPUART1_CR1 = '1'	Enables FIFO. BDMA will then use TXFNF (TXFIFO Not Full) flag for generating the BDMA requests.
TCIE of LPUART1_CR1 = '0'	Disables interrupt when the transmit buffer is empty.
UE of LPUART1_CR1 = '1'	Enables BDMA.
TE of LPUART1_CR1 = '1'	Enables the LPUART1.
TXE of LPUART1_CR1 = '1'	Enables transmission.
DMAT of LPUART1_CR3 = '1'	Enables the BDMA mode for transmission.

Respect the sequence described in [Table 43](#) to enable LPUART1.

**Table 43. LPUART1 Initial programming (LPUART1\_Start)**

Register content	Related actions
TCCF of LPUART1_ICR = '1'	Clears the TC flag, to avoid immediate interrupt generation, which would clear the D3_PendClear[1] in EXTI.
TCIE of LPUART1_CR1 = '1'	Enables interrupt when the transmit buffer is empty.

### 7.3.3 Overall description of the low-power application example based on LPUART1 transmission

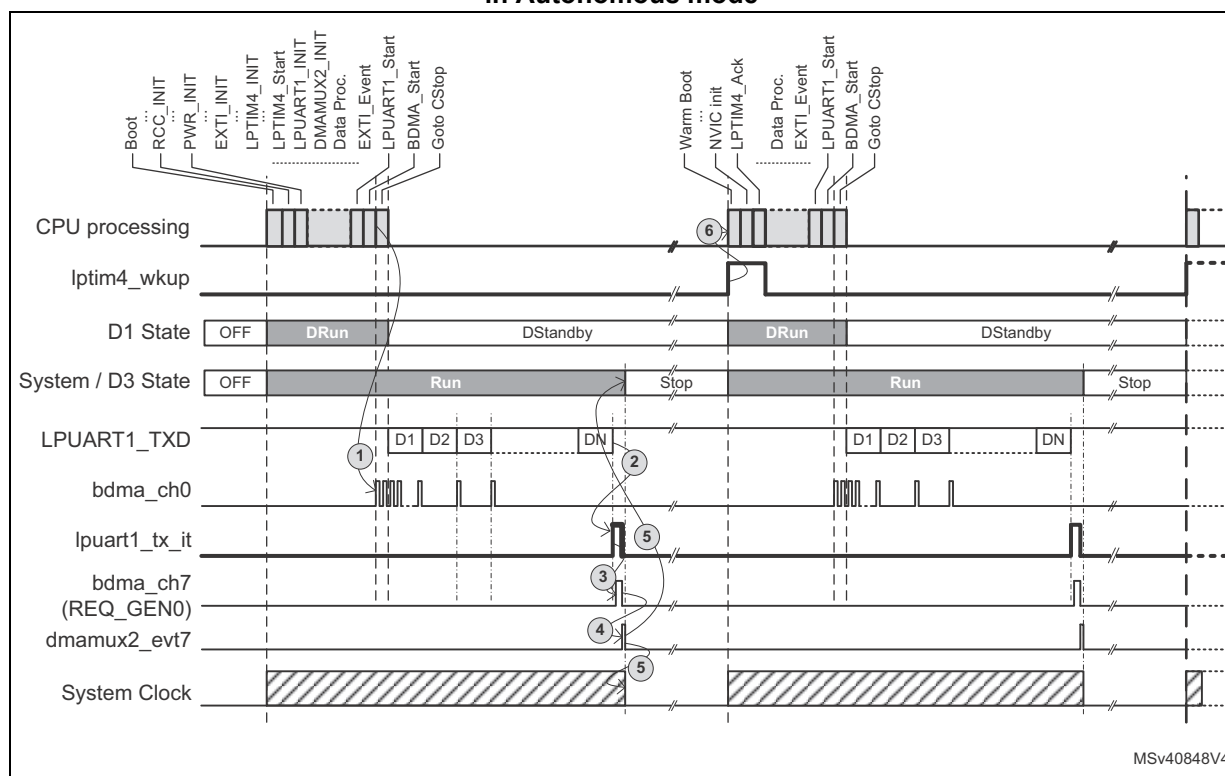

After a Power-on reset, the CPU perform the following operations:

1. Boot sequence (not described here).
2. Full initialization of RCC, PWR, EXTI, LPUART1, GPIOs, LPTIM4, DMAMUX2, BDMA and NVIC.  
Only the relevant steps of RCC, EXTI, PWR, LPUART1, BDMA and DMAMUX2 initialization related to the Autonomous mode are described herein. Refer to the previous sections for additional details.
3. the CPU processes the data to be transferred and copies them to SRAM4.
4. the CPU generates a wakeup event (EXTI\_Event) to maintain D3 in Run mode when D1 enters DStandby.
5. the CPU enables the BDMA to start LPUART transmission and goes to Stop mode. As it is allowed to do so, D1 domain enters DStandby while D3 remains in Run mode. The data stored in SRAM4 are retained while the D1 domain is in DStandby mode.
6. As soon as the BDMA is enabled, it serves the request from LPUART1 in order to fill its TX-FIFO. In parallel, serial data transmission can start.
7. When the expected amount of data has been transmitted (NDT bits of BDMA\_CNDTR0 set to 0), the BDMA no longer provides data to the LPUART1. The LPUART1 generates an interrupt when the TX-FIFO and the transmit buffer are empty.
8. This interrupt triggers DMAMUX2 REQ\_GEN0, thus activating a data transfer via BDMA channel 7 (BDMA\_Ch7). This transfer clears LPUART1 TC flag, and the **lpuart1\_tx\_it** is reset to '0'.
9. The end of this transfer triggers a `dmamux2_evt7` signal which is used to clear the wakeup request generated by the CPU.
10. As a consequence, the D3 domain (i.e. the system) enters Stop mode and the system clock is gated. LPTIM4 still operates since it uses **ck\_Isi** clock.

11. LPTIM4 `lptim4_wkup` interrupt wakes up the system. The device exits from Stop mode with the HSI clock. the CPU must restore the proper clock configuration during the warm re-boot sequence and perform the following tasks:
  - d) Acknowledge LPTIM4 wakeup interrupt,
  - e) Process the next data block and transfers them to SRAM4,
  - f) Generate again a wakeup event for D3 domain,
  - g) Start the BDMA.
  - h) Go back to CStop mode.

Note: The CPU does not need to initialize BDMA, DMAMUX2 and LPUART1 again.

**Figure 32. Timing diagram of LPUART1 transmission with D3 domain in Autonomous mode**

### 7.3.4 Alternate implementations

More power efficient implementations are also possible. As an example the system clock can be stopped once the data have been transferred to LPUART1 TX-FIFO, instead of remaining activated during the whole transmission as in the example presented above. In this case, the LPUART1 must use `ck_hsi` or `ck_csi` as kernel clock when the system switches from Run to Stop mode. LPUART1 must be programmed to wake up D3 domain when its TX-FIFO is almost empty. This asynchronous interrupt can be used as trigger by the `REQ_GENx` of the DMAMUX2, which will perform a given number (e.g. 14) of data transfers to LPUART1\_TDR and then switch back the D3 domain to Stop mode. This implementation is possible because the LPUART1 can request the kernel clock as long as the TX-FIFO and transmit buffer are not empty.

## 7.4 Other low-power applications

Other peripherals located in D3 domain, such as I2C4, SPI6, SAI4 or ADC3, can be used to implement low-power applications.

## 8 Reset and Clock Control (RCC)

The RCC block manages the clock and reset generation for the whole microcontroller.

The RCC block is located in the D3 domain (refer to [Section 6: Power control \(PWR\)](#) for a detailed description).

The operating modes this section refers to are defined in [Section 6.6.1: Operating modes](#) of the PWR block.

### 8.1 RCC main features

#### Reset block

- Generation of local and system reset
- Bidirectional pin reset allowing to reset the microcontroller or external devices
- Hold Boot function
- WWDG reset supported

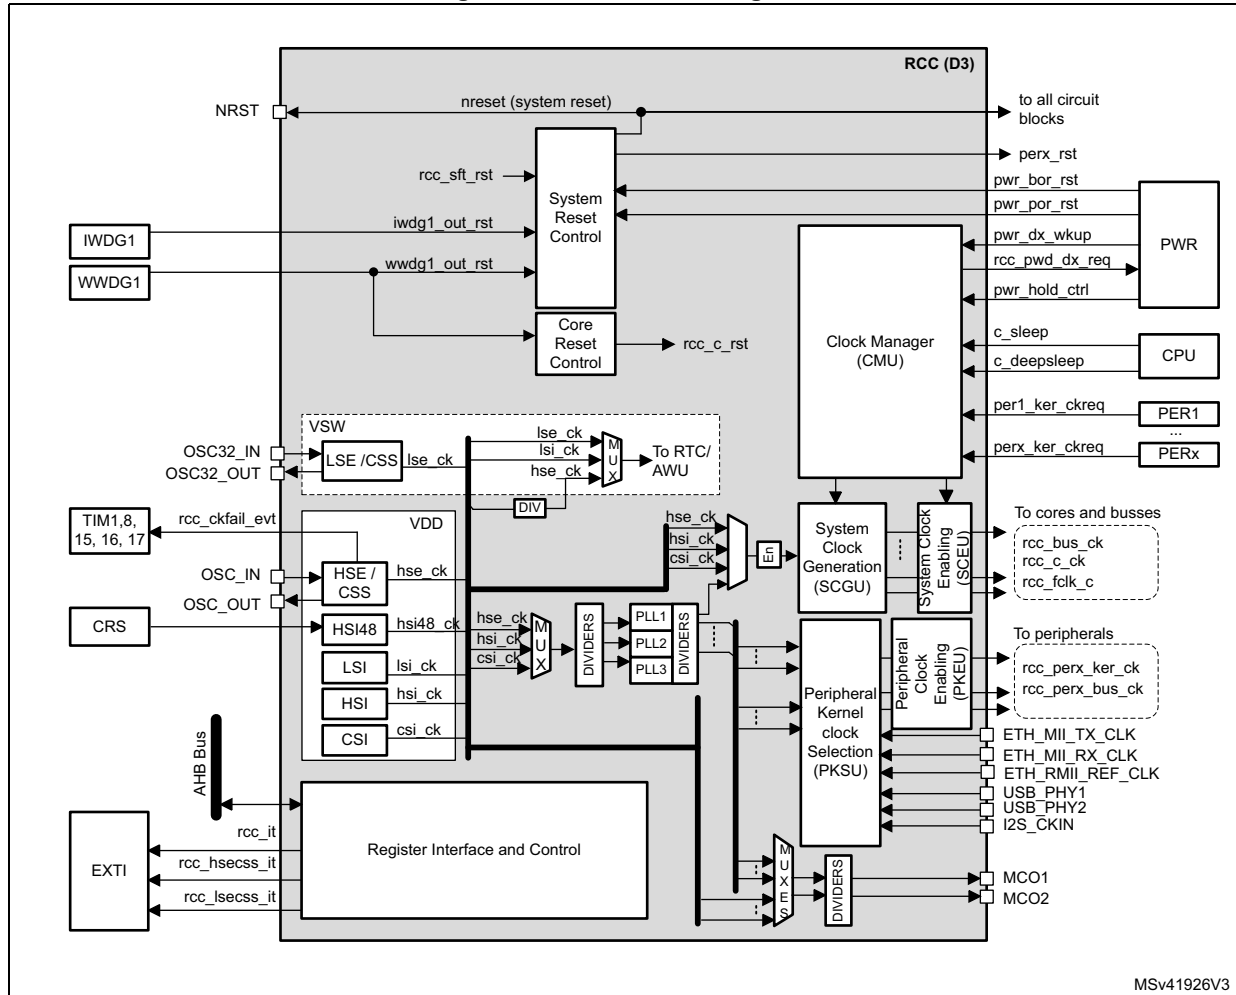

#### Clock generation block

- Generation and dispatching of clocks for the complete device
- 3 separate PLLs using integer or fractional ratios
- Possibility to change the PLL fractional ratios on-the-fly
- Smart clock gating to reduce power dissipation
- 2 external oscillators:
  - High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 48 MHz frequency
  - Low-speed external oscillator (LSE) for the 32 kHz crystals
- 4 internal oscillators
  - High-speed internal oscillator (HSI)
  - 48 MHz RC oscillator (HSI48)
  - Low-power Internal oscillator (CSI)
  - Low-speed internal oscillator (LSI)
- Buffered clock outputs for external devices
- Generation of two types of interrupts lines:
  - Dedicated interrupt lines for clock security management
  - One general interrupt line for other events
- Clock generation handling in Stop and Standby mode
- D3 domain Autonomous mode

## 8.2 RCC block diagram

Figure 33 shows the RCC block diagram.

Figure 33. RCC Block diagram

## 8.3 RCC pins and internal signals

Table 44 lists the RCC inputs and output signals connected to package pins or balls.

Table 44. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input

**Table 44. RCC input/output signals connected to package pins or balls (continued)**

Signal name	Signal type	Description
OSC_OUT	O	System oscillator output
MCO1	O	Output clock 1 for external devices
MCO2	O	Output clock 2 for external devices
I2S_CKIN	I	External kernel clock input for digital audio interfaces: SPI/I2S, SAI, and DFSDM
ETH_MII_TX_CLK	I	External TX clock provided by the Ethernet MII interface
ETH_MII_RX_CLK	I	External RX clock provided by the Ethernet MII interface
ETH_RMII_REF_CLK	I	External reference clock provided by the Ethernet RMII interface
USB_PHY1	I	USB clock input provided by the external USB PHY
USB_PHY2	I	USB clock input provided by the external USB PHY

The RCC exchanges a lot of internal signals with all components of the product, for that reason, the [Table 44](#) only shows the most significant internal signals.

**Table 45. RCC internal input/output signals**

New Signal name	Signal type	Description
rcc_it	O	General interrupt request line
rcc_hsecss_it	O	HSE clock security failure interrupt
rcc_lsecss_it	O	LSE clock security failure interrupt
rcc_ckfail_evt	O	Event indicating that a HSE clock security failure is detected. This signal is connected to TIMERS
nreset	I/O	System reset
iwdg1_out_rst	I	Reset line driven by the IWDG1, indicating that a timeout occurred.
wwdg1_out_rst	I	Reset line driven by the WWDG1, indicating that a timeout occurred.
pwr_bor_rst	I	Brownout reset generated by the PWR block
pwr_por_rst	I	Power-on reset generated by the PWR block
pwr_vsw_rst	I	Power-on reset of the VSW domain generated by the PWR block
rcc_perx_rst	O	Reset generated by the RCC for the peripherals.
pwr_d[3:1]_wkup	I	Wake-up domain request generated by the PWR. Generally used to restore the clocks a domain when this domain exits from DStop
rcc_pwd_d[3:1]_req	O	Low-Power request generated by the RCC. Generally used to ask to the PWR to set a domain into low-power mode, when a domain is in DStop.
pwr_hold_ctrl	I	Signals generated by the PWR, in order to set the processor into CStop when exiting from system Stop mode.
c_sleep	I	Signal generated by the CPU, indicating if the CPU is in CRun, CSleep or CStop.
c_deepsleep	I	

Table 45. RCC internal input/output signals (continued)

New Signal name	Signal type	Description
perx_ker_ckreq	I	Signal generated by some peripherals in order to request the activation of their kernel clock.
rcc_perx_ker_ck	O	Kernel clock signals generated by the RCC, for some peripherals.
rcc_perx_bus_ck	O	Bus interface clock signals generated by the RCC for peripherals.
rcc_bus_ck	O	Clocks for APB (rcc_apb_ck), AHB (rcc_ahb_ck) and AXI (rcc_axi_ck) bridges generated by the RCC.
rcc_c_ck	O	Clock for the CPU, generated by the RCC.
rcc_fclk_c	O	

## 8.4 RCC reset block functional description

Several sources can generate a reset:

- An external device via NRST pin
- A failure on the supply voltage applied to  $V_{DD}$
- A watchdog timeout
- A software command

The reset scope depends on the source that generates the reset. Three reset categories exist:

- Power-on/off reset
- System reset
- Local resets

### 8.4.1 Power-on/off reset

The power-on/off reset (**pwr\_por\_rst**) is generated by the power controller block (PWR). It is activated when the input voltage ( $V_{DD}$ ) is below a threshold level. This is the most complete reset since it resets the whole circuit, except the backup domain. The power-on/off reset function can be disabled through PDR\_ON pin (see [Section 6.5: Power supply supervision](#)).

Refer to [Table 46: Reset distribution summary](#) for details.

### 8.4.2 System reset

A system reset (**nreset**) resets all registers to their default values except for the reset status flags in the RCC\_RSR (or RCC\_C1\_RSR) register, the debug features, the Flash memory and the Backup domain registers.

A system reset can be generated from one of the following sources:

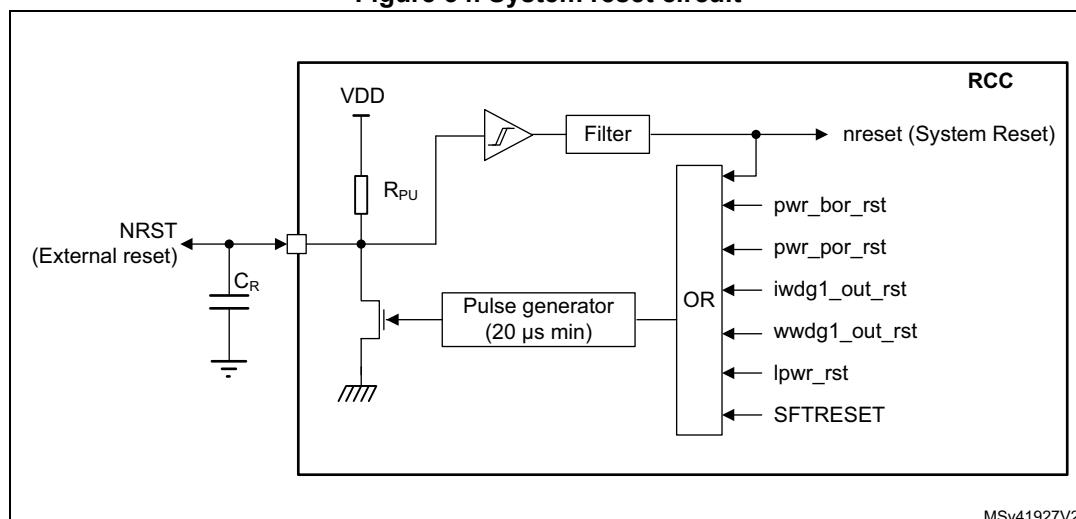

- A reset from NRST pin (external reset)
- A reset from the power-on/off reset block (**pwr\_por\_rst**)
- A reset from the brownout reset block (**pwr\_bor\_rst**)  
Refer to [Section 6.5.2: Brownout reset \(BOR\)](#) for a detailed description of the BOR function.
- A reset from the independent watchdogs (**iwdg1\_out\_rst**)
- A software reset from the Cortex<sup>®</sup>-M7 core  
It is generated via the SYSRESETREQ signal issued by the Cortex<sup>®</sup>-M7 core. This signal is also named SFTRESET in this document.
- A reset from the window watchdogs depending on WWDG configuration (**wwdg1\_out\_rst**)
- A reset from the low-power mode security reset, depending on option byte configuration (**lpwr[2:1]\_rst**)

*Note:* The SYSRESETREQ bit in Cortex<sup>®</sup>-M7 Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex<sup>®</sup>-M7 with FPU technical reference manual for more details (see <http://infocenter.arm.com>).

As shown in [Figure 34](#), some internal sources (such as **pwr\_por\_rst**, **pwr\_bor\_rst**, **iwdg1\_out\_rst**) perform a system reset of the circuit, which is also propagated to the NRST pin to reset the connected external devices. The pulse generator guarantees a minimum reset pulse duration of 20 μs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted Low.

*Note:* It is not recommended to let the NRST pin unconnected. When it is not used, connect this pin to ground via a 10 to 100 nF capacitor ( $C_R$  in [Figure 34](#)).

**Figure 34. System reset circuit**

### 8.4.3 Local resets

#### CPU reset

The CPU can reset itself by means of the CPURST bit in [RCC AHB3 Reset Register \(RCC\\_AHB3RSTR\)](#).

#### Domain reset

Some resets also dependent on the domain status. For example, when D1 domain exits from DStandby, it is reset (**d1\_rst**). The same mechanism applies to D2.

When the system exits from Standby mode, a **stby\_rst** reset is applied. The **stby\_rst** signal generates a reset of the complete V<sub>CORE</sub> domain as long the V<sub>CORE</sub> voltage provided by the internal regulator is not valid.

[Table 46](#) gives a detailed overview of reset sources and scopes.

**Table 46. Reset distribution summary**

Reset source	Reset name	D1 CPU	D1 Interconnect	D1 Peripherals	D1 Debug	WWDG1	D2 Interconnect	D2 Peripherals	D3 Peripherals	IWDG1	FLASH	RTC domain	Backup RAM	System Supply	NRST pin	Comments
Pin	NRST	x	x	x	-	x	x	x	x	x	-	-	-	-	x	<ul style="list-style-type: none"> <li>– Resets D1 and D2 domains, and all their peripherals</li> <li>– Resets D3 domain peripherals</li> <li>– Resets V<sub>DD</sub> domain: IWDG1, LDO...</li> <li>– Debug features, Flash memory, RTC and backup RAM are not reset</li> </ul>
PWR	pwr_bor_rst	x	x	x	-	x	x	x	x	x	-	-	-	-	x	– Same as pin reset. The pin is asserted as well.
	pwr_por_rst	x	x	x	x	x	x	x	x	x	-	-	x	x		<ul style="list-style-type: none"> <li>– Same as <b>pwr_bor_rst</b> reset, plus: Reset of the Flash memory digital block (including the option byte loading).</li> <li>– Reset of the debug block</li> </ul>
	lpwr_rst	x	x	x	-	x	x	x	x	x	-	-	-	-	x	– The low-power mode security reset has the same scope than <b>pwr_por_rst</b> . Refer to <a href="#">Section 8.4.5: Low-power mode security reset (lpwr_rst)</a> for additional information.

Table 46. Reset distribution summary (continued)

Reset source	Reset name	D1 CPU	D1 Interconnect	D1 Peripherals	D1 Debug	WWDG1	D2 Interconnect	D2 Peripherals	D3 Peripherals	IWDG1	FLASH	RTC domain	Backup RAM	System Supply	NRST pin	Comments
RCC	BDRST	-	-	-	-	-	-	-	-	-	-	x	-	-	-	- The backup domain reset can be triggered by software. Refer to <a href="#">Section 8.4.6: Backup domain reset</a> for additional information
	d1_rst	x	x	x	x	x	-	-	-	-	-	-	-	-	-	- Resets D1 domain, and all its peripherals, when the domain exits DStandby mode.
	d2_rst	-	-	-	-	-	x	x	-	-	-	-	-	-	-	- Resets D2 domain, and all its peripherals, when the domain exits DStandby mode.
	stby_rst	x	x	x	x	x	x	x	x	-	-	-	-	-	-	- When the device exits Standby mode, a reset of the complete V <sub>CORE</sub> domain is performed as long the V <sub>CORE</sub> voltage is not valid. The V <sub>CORE</sub> is supplied by the internal regulator. NRST signal is not asserted.
	CPURST	x	-	-	-	x	-	-	-	-	-	-	-	-	-	- This reset is generated by software through the bit located into <a href="#">RCC AHB3 Reset Register (RCC_AHB3RSTR)</a> . - Resets the CPU, and the WWDG1 block
CPU	SFTRESET	x	x	x	-	x	x	x	x	x	-	-	-	-	x	- This reset is generated by software when writing SYSRESETREQ bit located into AIRCR register of the Cortex <sup>®</sup> -M7 core. - Same scope as <b>pwr_bor_rst</b> reset.
Backup domain	pwr_vsw_rst	-	-	-	-	-	-	-	-	-	-	x	-	-	-	- This reset is generated by the backup domain when the V <sub>SW</sub> supply voltage is outside the operating range.
IWDG1	iwdg1_out_rst	x	x	x	-	x	x	x	x	x	-	-	-	-	x	- Same as <b>pwr_bor_rst</b> reset.
WWDG1	wwdg1_out_rst	x	x	x	-	x	x	x	x	x	-	-	-	-	x	- Same as <b>pwr_bor_rst</b> reset.

### 8.4.4 Reset source identification

The CPU can identify the reset source by checking the reset flags in the RCC\_RSR (or RCC\_C1\_RSR) register.

The CPU can reset the flags by setting RMVF bit.

[Table 47](#) shows how the status bits of RCC\_RSR (or RCC\_C1\_RSR) register behaves, according to the situation that generated the reset. For example when an IWDG1 timeout occurs (line #10), if the CPU is reading the RCC\_RSR (or RCC\_C1\_RSR) register during

the boot phase, both PINRSTF and IWDG1RSTF bits are set, indicating that the IWDG1 also generated a pin reset.

**Table 47. Reset source identification (RCC\_RSR)<sup>(1)</sup>**

#	Situations Generating a Reset	LPWRRSTF	WWDG1RSTF	IWDG1RSTF	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	D2RSTF	D1RSTF	CPURSTF
1	Power-on reset (pwr_por_rst)	0	0	0	0	1	1	1	1	1	1
2	Pin reset (NRST)	0	0	0	0	0	1	0	0	0	1
3	Brownout reset (pwr_bor_rst)	0	0	0	0	0	1	1	0	0	1
4	System reset generated by CPU (SFTRESET)	0	0	0	1	0	1	0	0	0	1
5	CPU reset (CPURST)	0	0	0	0	0	0	0	0	0	1
6	WWDG1 reset (wwdg1_out_rst)	0	1	0	0	0	1	0	0	0	1
8	IWDG1 reset (iwdg1_out_rst)	0	0	1	0	0	1	0	0	0	1
10	D1 exits DStandby mode	0	0	0	0	0	0	0	0	1	0
11	D2 exits DStandby mode	0	0	0	0	0	0	0	1	0	0
12	D1 erroneously enters DStandby mode or CPU erroneously enters CStop mode	1	0	0	0	0	1	0	0	0	1

1. Grayed cells highlight the register bits that are set.

#### 8.4.5 Low-power mode security reset (lpwr\_rst)

To prevent critical applications from mistakenly enter a low-power mode, two low-power mode security resets are available. When enabled through nRST\_STOP\_D1 option bytes, a system reset is generated if the following conditions are met:

- CPU accidentally enters CStop mode  
This type of reset is enabled by resetting nRST\_STOP\_D1 user option byte. In this case, whenever the CPU CStop mode entry sequence is successfully executed, a system reset is generated.
- D1 domain accidentally enters DStandby mode  
This type of reset is enabled by resetting nRST\_STDBY\_D1 user option byte. In this case, whenever a D1 domain DStandby mode entry sequence is successfully executed, a system reset is generated.

LPWRRSTF bits in *RCC Reset Status Register (RCC\_RSR)* indicates that a low-power mode security reset occurred (see line #12 in *Table 47*).

**lpwr\_rst** is activated when a low-power mode security reset due to D1 or CPU occurred.

Refer to *Section 3.3.11: FLASH option bytes* for additional information.

### 8.4.6 Backup domain reset

A backup domain reset is generated when one of the following events occurs:

- A software reset, triggered by setting BDRST bit in the [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#). All RTC registers and the RCC\_BDCR register are reset to their default values. The backup RAM is not affected.
- $V_{SW}$  voltage is outside the operating range. All RTC registers and the RCC\_BDCR register are reset to their default values. In this case the content of the backup RAM is no longer valid.

There are two ways to reset the backup RAM:

- through the Flash memory interface by requesting a protection level change from 1 to 0
- when a tamper event occurs.

Refer to [Section 6.4.4: Backup domain](#) section of PWR block for additional information.

### 8.4.7 Power-on and wakeup sequences

For detailed diagrams refer to [Section 6.4.1: System supply startup](#) in the PWR section.

The time interval between the event which exits the product from a low-power and the moment where the CPU is able to execute code, depends on the system state and on its configuration. [Figure 35](#) shows the most usual examples.

#### Power-on wakeup sequence

The power-on wakeup sequence shown in [Figure 35](#) gives the most significant phases of the power-on sequence. It is the longest sequence since the circuit was not powered. Note that this sequence remains unchanged, whatever  $V_{BAT}$  was present or not.

#### Boot from pin reset

When a pin reset occurs,  $V_{DD}$  is still present. As a result:

- The regulator settling time is faster since the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.
- The Flash memory power recovery delay can also be skipped if the Flash memory was enabled when the NRST occurred.

*Note:* The boot sequence is similar for *pwr\_bor\_rst*, *lpwr\_rst*, *STFxRESET*, *iwdg1\_out\_rst* and *wwdg1\_out\_rst* (if *WW1RSC* = '1').

#### Boot from system Standby

When waking up from system Standby, the reference voltage is stable since  $V_{DD}$  has not been removed. As a result, the regulator settling time is fast. Since  $V_{CORE}$  was not present, the restart delay for the HSI, the Flash memory power recovery and the option byte reloading cannot be skipped.

### Restart from system Stop

When restarting from system Stop,  $V_{DD}$  is still present. As a result, the sequence is mainly composed of two steps:

1. Regulator settling time to reach VOS3 (default voltage)
2. HSI/CSI restart delay. This step can be skipped if HSIKERON or CSIKERON bit, in [RCC Source Control Register \(RCC\\_CR\)](#) is set to '1'.

### Boot from domain DStandby

The boot sequence of a domain from domain DStandby is mainly composed of two steps:

1. The power switch settling time (the regulator is already activated).
2. The Flash memory power recovery.

### Restart from domain DStop

The restart sequence of a domain from domain DStop is mainly composed of the handshake between the RCC, EXTI and PWR blocks.

Figure 35. Boot sequences versus system states

## 8.5 RCC clock block functional description

The RCC provides a wide choice of clock generators:

- HSI (High-speed internal oscillator) clock: ~ 8, 16, 32 or 64 MHz
- HSE (High-speed external oscillator) clock: 4 to 48 MHz
- LSE (Low-speed external oscillator) clock: 32 kHz
- LSI (Low-speed internal oscillator) clock: ~ 32 kHz
- CSI (Low-power internal oscillator) clock: ~4 MHz
- HSI48 (High-speed 48 MHz internal oscillator) clock: ~48 MHz

It offers a high flexibility for the application to select the appropriate clock for CPU and peripherals, in particular for peripherals that require a specific clock such as Ethernet, USB OTG-FS and HS, SPI/I2S, SAI and SDMMC.

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to 3 PLLs; each of them can be configured with integer or fractional ratios.

As shown in the [Figure 36](#), the RCC offers 2 clock outputs (MCO1 and MCO2), with a great flexibility on the clock selection and frequency adjustment.

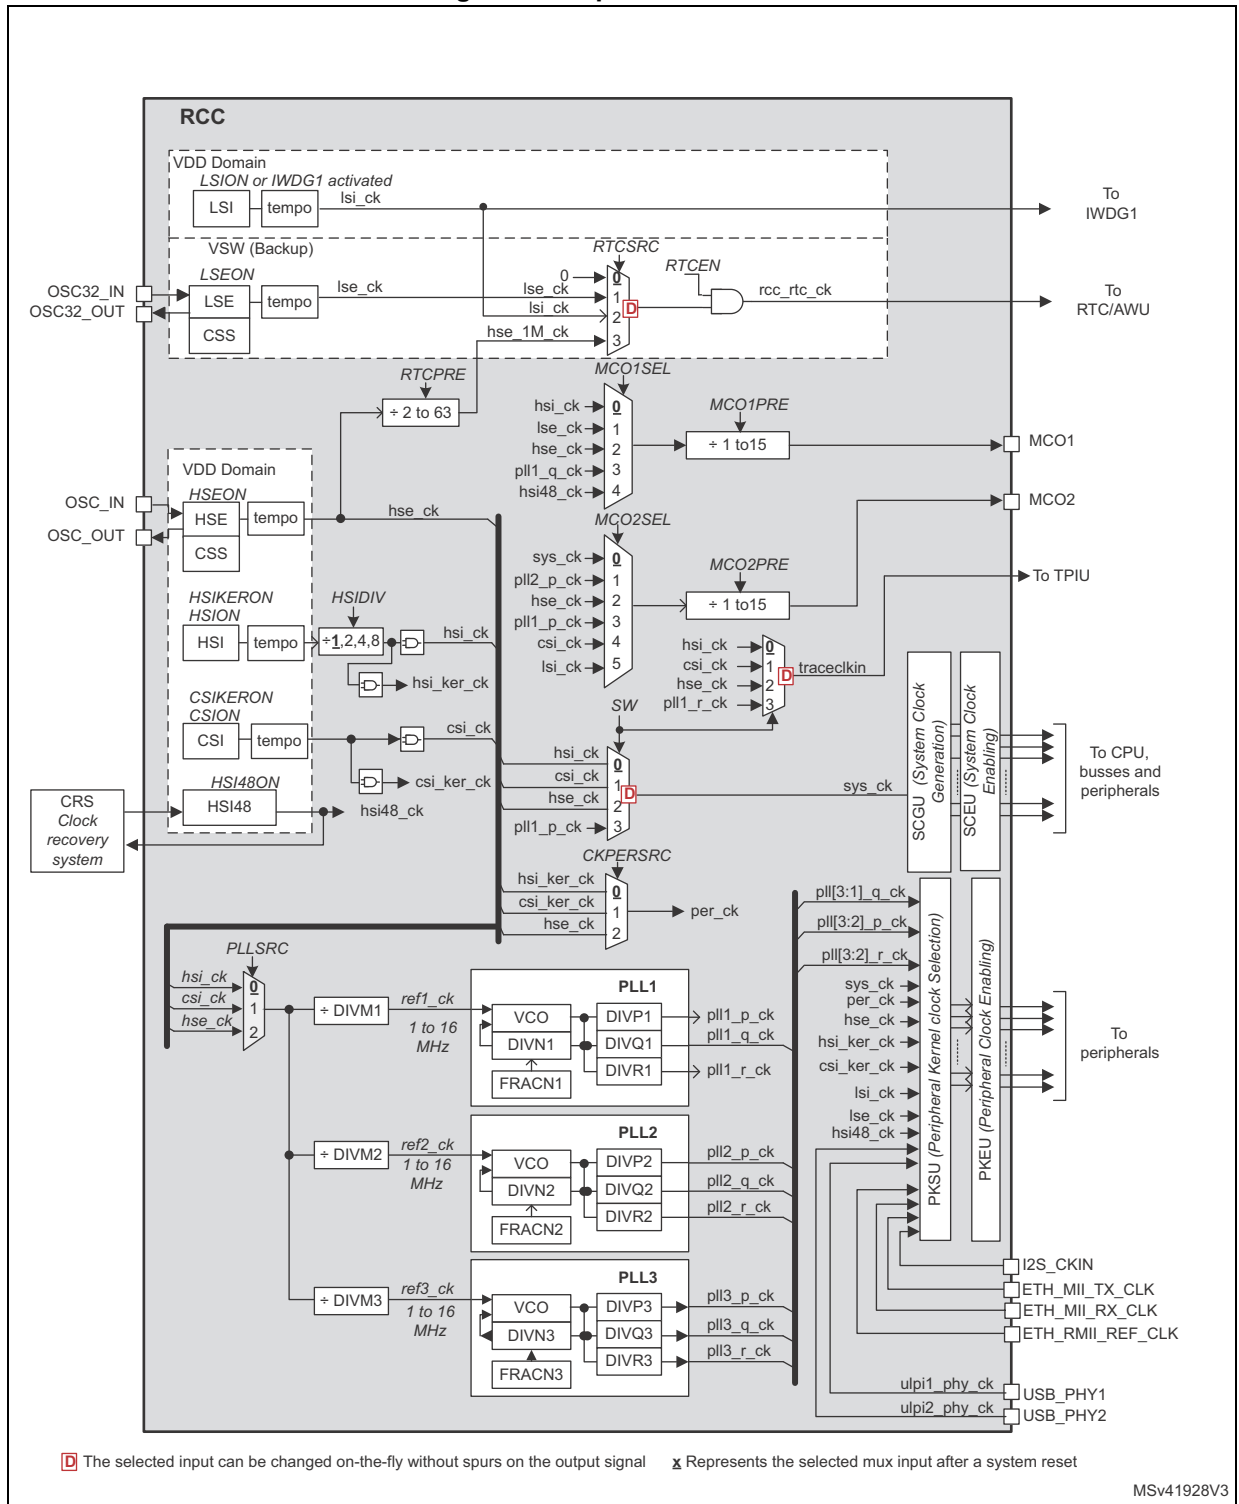

The SCGU block (System Clock Generation Unit) contains several prescalers used to configure the CPU and bus matrix clock frequencies.

The PKSU block (Peripheral Kernel clock Selection Unit) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PKEU (Peripheral Kernel clock Enable Unit) and SCEU (System Clock Enable Unit) blocks perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.

Figure 36. Top-level clock tree

### 8.5.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstanding, the following terms are used in this document:

- Peripheral clocks
 

The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clock are available:

  - The bus interface clocks
  - The kernel clocks

A peripheral receives from the RCC a bus interface clock in order to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (e.g. RNG, TIMx).

Some peripherals also require a dedicated clock to handle the interface function. This clock is named “kernel clock”. As an example, peripherals such as SAI have to generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.
- CPU clocks
 

The CPU clock is the clock provided to the CPU. It is derived from the system clock (**sys\_ck**).
- Bus matrix clocks
 

The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI). These clocks are derived from the system clock (**sys\_ck**).

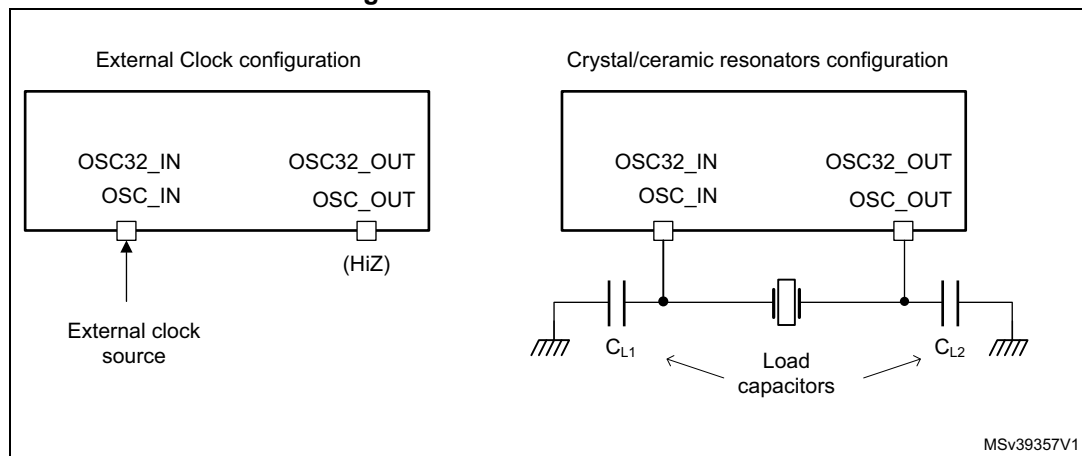

### 8.5.2 Oscillators description

#### HSE oscillator

The HSE block can generate a clock from two possible sources:

- External crystal/ceramic resonator
- External clock source

Figure 37. HSE/LSE clock source

### External clock source (HSE bypass)

In this mode, an external clock source must be provided to OSC\_IN pin. This mode is selected by setting the HSEBYP and HSEON bits of the [RCC Source Control Register \(RCC\\_CR\)](#) to '1'. The external clock source (square, sinus or triangle) with ~50% duty cycle has to drive the OSC\_IN pin while the OSC\_OUT pin should be left HI-Z (see [Figure 37](#)).

### External crystal/ceramic resonator

The oscillator is enabled by setting the HSEBYP bit to '0' and HSEON bit to '1'.

The HSE can be used when the product requires a very accurate high-speed clock.

The associated hardware configuration is shown in [Figure 37](#): the resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag of the [RCC Source Control Register \(RCC\\_CR\)](#), indicates whether the HSE oscillator is stable or not. At startup, the `hse_ck` clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC Clock Source Interrupt Enable Register \(RCC\\_CIER\)](#).

The HSE can be switched ON and OFF through the HSEON bit. Note that the HSE cannot be switched OFF if one of the two conditions is met:

- The HSE is used directly (via software mux) as system clock
- The HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSEON bit to '0'.

The HSE is automatically disabled by hardware, when the system enters Stop or Standby mode (refer to [Section 8.5.7: Handling clock generators in Stop and Standby mode](#) for additional information).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

### LSE oscillator

The LSE block can generate a clock from two possible sources:

- External crystal/ceramic resonator
- External user clock

### External clock source (LSE bypass)

In this mode, an external clock source must be provided to OSC32\_IN pin. The input clock can have a frequency up to 1 MHz. This mode is selected by setting the LSEBYP and LSEON bits of [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#) to '1'. The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32\_IN pin while the OSC32\_OUT pin should be left HI-Z (see [Figure 37](#)).

### External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions.

The LSERDY flag of the [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC Clock Source Interrupt Enable Register \(RCC\\_CIER\)](#).

The LSE oscillator is switched ON and OFF using the LSEON bit. The LSE remains enabled when the system enters Stop or Standby mode.

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for other application components.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. The driving capability can be changed dynamically from high drive to medium high drive, and then to medium low drive.

### HSI oscillator

The HSI block provides the default clock to the product.

The HSI is a high-speed internal RC oscillator which can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:

- Low-cost clock source since no external crystal is required
- Faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The HSI can be switched ON and OFF using the HSION bit. Note that the HSI cannot be switched OFF if one of the two conditions is met:

- The HSI is used directly (via software mux) as system clock
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSION bit to '0'.

Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to '1'). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to [Section : CSS on HSE](#)). The HSI can be disabled or not when the system enters Stop mode, please refer to [Section 8.5.7: Handling clock generators in Stop and Standby mode](#) for additional information.

In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

*Note:* The HSI can remain enabled when the system is in Stop mode (see [Section 8.5.7](#) for additional information).

*HSION, HSIRDY and HSIDIV bits are located in the [RCC Source Control Register \(RCC\\_CR\)](#).*

### HSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of  $ACC_{HSI}$  (refer to the product datasheet for more information).

After a power-on reset, the factory calibration value is loaded in the HSICAL[11:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[5:0] bits.

*Note:* *HSICAL[11:0] and HSITRIM[5:0] bits are located in the [RCC Internal Clock Source Calibration Register \(RCC\\_ICSCR\)](#).*

### CSI oscillator

The CSI is a low-power RC oscillator which can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- Low-cost clock source since no external crystal is required
- Faster startup time than HSE (a few microseconds)
- Very low-power consumption,

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by hardware.

The CSI cannot be switched OFF if one of the two conditions is met:

- The CSI is used directly (via software mux) as system clock
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the CSION bit to '0'.

The CSI can be disabled or not when the system enters Stop mode (refer to [Section 8.5.7: Handling clock generators in Stop and Standby mode](#) for additional information).

In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.

Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application has to take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency precision.

*Note:* *CSION and CSIRDY bits are located in the [RCC Source Control Register \(RCC\\_CR\)](#).*

#### **CSI calibration**

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by STMicroelectronics to achieve accuracy of  $ACC_{CSI}$  (refer to the product datasheet for more information).

After reset, the factory calibration value is loaded in the CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM[4:0] bits.

*Note:* *Bits CSICAL[7:0] and CSITRIM[4:0] are located into the [RCC Internal Clock Source Calibration Register \(RCC\\_ICSCR\)](#)*

#### **HSI48 oscillator**

The HSI48 is an RC oscillator that delivers a 48 MHz clock that can be used directly as kernel clock for some peripherals.

The HSI48 oscillator mainly aims at providing a high precision clock to the USB peripheral by means of a special Clock Recovery System (CRS) circuitry, which could use the USB SOF signal, the LSE, or an external signal, to automatically adjust the oscillator frequency on-the-fly, in very small granularity.

The HSI48 oscillator is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, this oscillator is free running and thus subject to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of  $ACC_{HSI48}$  (refer to the product datasheet of the for more information).

For more details on how to configure and use the CRS, please refer to [Section 9: Clock recovery system \(CRS\)](#).

The HSI48RDY flag indicates whether the HSI48 oscillator is stable or not. At startup, the HSI48 output clock is not released until this bit is set by hardware.

The HSI48 can be switched ON and OFF using the HSI48ON bit.

The HSI48 clock can also be driven to the MCO1 multiplexer and used as clock source for other application components.

*Note:* *HSI48ON and HSI48RDY bits are located in the [RCC Source Control Register \(RCC\\_CR\)](#).*

### LSI oscillator

The LSI acts as a low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and Auto-Wakeup Unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (refer to [Section 8.5.7: Handling clock generators in Stop and Standby mode](#) for additional information).

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the [RCC Clock Source Interrupt Enable Register \(RCC\\_CIER\)](#).

In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

*Note:* Bits LSION and LSIRDY are located into the [RCC Clock Control and Status Register \(RCC\\_CSR\)](#).

## 8.5.3 Clock Security System (CSS)

### CSS on HSE

The clock security system can be enabled by software via the HSECSSON bit. The HSECSSON bit can be enabled even when the HSEON is set to '0'.

The CSS on HSE is enabled by the hardware when the HSE is enabled and ready, and HSECSSON set to '1'.

The CSS on HSE is disabled when the HSE is disabled. As a result, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software.

The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode (see [Section 8.4.2: System reset](#)).

If a failure is detected on the HSE clock, the system automatically switches to the HSI in order to provide a safe clock. The HSE is then automatically disabled, a clock failure event is sent to the break inputs of advanced-control timers (TIM1, TIM8, TIM15, TIM16, and TIM17), and an interrupt is generated to inform the software about the failure (CSS interrupt: **rcc\_hsecss\_it**), thus allowing the MCU to perform rescue operations. If the HSE output was used as clock source for PLLs when the failure occurred, the PLLs are also disabled.

If an HSE clock failure occurs when the CSS is enabled, the CSS generates an interrupt which causes the automatic generation of an NMI. The HSECSSF flag in [RCC Clock Source Interrupt Flag Register \(RCC\\_CIFR\)](#) is set to '1' to allow the application to identify the failure source. The NMI routine is executed indefinitely until the HSECSSF bit is cleared. As a consequence, the application has to clear the HSECSSF flag in the NMI ISR by setting the HSECSSC bit in the [RCC Clock Source Interrupt Clear Register \(RCC\\_CICR\)](#).

### CSS on LSE

A clock security system on the LSE oscillator can be enabled by software by programming the LSECSSON bit in the *RCC Backup Domain Control Register (RCC\_BDCR)*.

This bit can be disabled only by hardware when the following conditions are met:

- after a pwr\_vsw\_rst ( $V_{SW}$  software reset)
- or after a failure detection on LSE.

LSECSSON bit must be written after the LSE is enabled (LSEON bit set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through the RTCSEL bit.

The CSS on LSE works in all modes (Run, Stop and Standby) except VBAT.

If an LSE failure is detected, the LSE clock is no more delivered to the RTC but the value of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.

A wakeup is generated in Standby mode. In other modes an interrupt (**rcc\_lsecss\_it**) can be sent to wake up the software. The software must then disable the LSECSSON bit, stop the defective LSE (clear LSEON bit), and can change the RTC clock source (no clock or LSI or HSE) through RTCSEL bits, or take any required action to secure the application.

### 8.5.4 Clock output generation (MCO1/MCO2)

Two micro-controller clock output (MCO) pins, MCO1 and MCO2, are available. A clock source can be selected for each output. The selected clock can be divided thanks to configurable prescaler (refer to *Figure 36* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1[2:0], MCO2PRE[3:0] and MCO2[2:0] located in the *RCC Clock Configuration Register (RCC\_CFGR)*.

The GPIO port corresponding to each MCO pin, has to be programmed in alternate function mode.

The clock provided to the MCOs outputs must not exceed the maximum pin speed (refer to the product datasheet for information on the supported pin speed).

### 8.5.5 PLL description

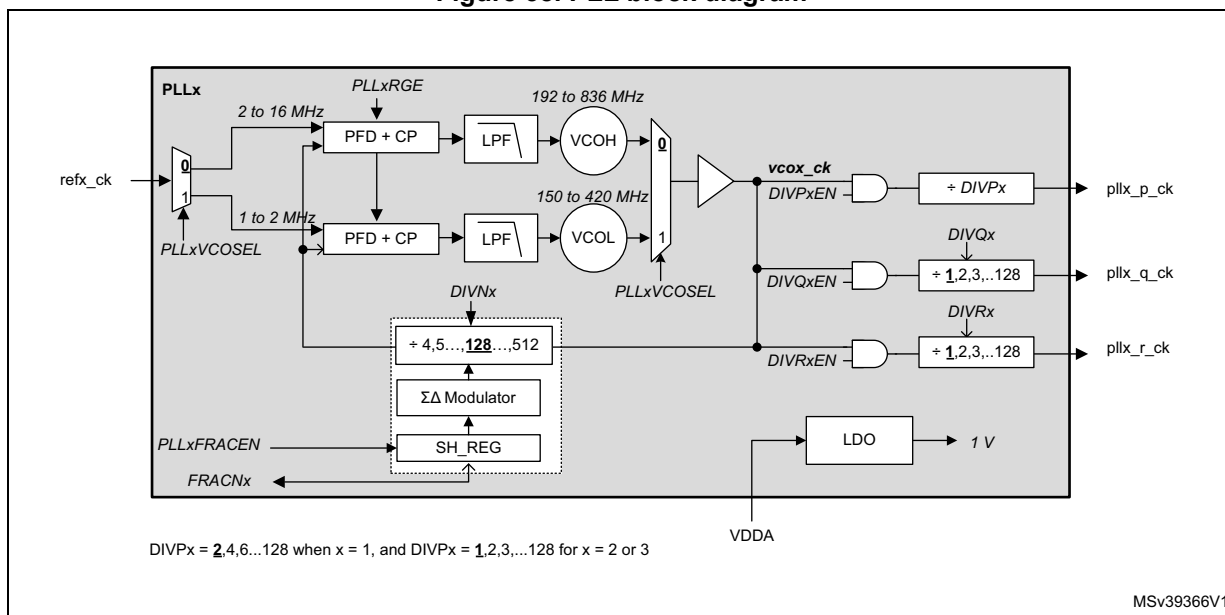

The RCC features three PLLs:

- A main PLL, PLL1, which is generally used to provide clocks to the CPU and to some peripherals.
- Two dedicated PLLs, PLL2 and PLL3, which are used to generate the kernel clock for peripherals.

The PLLs integrated into the RCC are completely independent. They offer the following features:

- Two embedded VCOs:
  - A wide-range VCO (VCOH)
  - A low-frequency VCO (VCOL)
- Input frequency range:
  - 1 to 2 MHz when VCOL is used
  - 2 to 16 MHz when VCOH is used
- Capability to work either in integer or Fractional mode
- 13-bit Sigma-Delta modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm.
- The Sigma-Delta modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
- Each PLL offer 3 outputs with post-dividers

Figure 38. PLL block diagram

The PLLs are controlled via RCC\_PLLxDIVR, RCC\_PLLxFRACR, RCC\_PLLCFGR and RCC\_CR registers.

The frequency of the reference clock provided to the PLLs (**refx\_ck**) must range from 1 to 16 MHz. The user application has to program properly the DIVMx dividers of the [RCC PLLs Clock Source Selection Register \(RCC\\_PLLCKSELR\)](#) in order to match this condition. In addition, the PLLxRGE of the [RCC PLLs Configuration Register \(RCC\\_PLLCFGR\)](#) field must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

The user application can then configure the proper VCO: if the frequency of the reference clock is lower or equal to 2 MHz, then VCOL must be selected, otherwise VCOH must be chosen. To reduce the power consumption, it is recommended to configure the VCO output to the lowest frequency.

DIVNx loop divider has to be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLs operate in integer mode when the value of SH\_REG (FRACNx shadow register) is set to '0'. The SH\_REG is updated with the FRACNx value when PLLxFRACEN bit goes from '0' to '1'. The Sigma-Delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

The PLLs can be enabled by setting PLLxON to '1'. The bits PLLxRDY indicate that the PLL is ready (i.e. locked).

**Note:** *Before enabling the PLLs, make sure that the reference frequency (**refx\_ck**) provided to the PLL is stable, so the hardware does not allow changing DIVMx when the PLLx is ON and it is also not possible to change PLLSRC when one of the PLL is ON.*

*The hardware prevents writing PLL1ON to '0' if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to sections [HSE oscillator](#), [HSI oscillator](#) and [CSI oscillator](#)).*

*The following PLL parameters cannot be changed once the PLL is enabled: DIVNx, PLLxRGE, PLLxVCOSEL, DIVPx, DIVQx, DIVRx, DIVPxEN, DIVQxEN and DIVRxEN.*

*To insure an optimal behavior of the PLL when one of the post-divider (DIVP, DIVQ or DIVR) is not used, the application shall set the enable bit (DIVyEN) as well as the corresponding post-divider bits (DIVP, DIVQ or DIVR) to '0'.*

*If the above rules are not respected, the PLL output frequency is not guaranteed.*

### Output frequency computation

When the PLL is configured in integer mode (SH\_REG = '0'), the VCO frequency ( $F_{VCO}$ ) is given by the following expression:

$$F_{VCO} = F_{REF\_CK} \times DIVN$$

$$F_{PLL\_y\_CK} = (F_{VCO} / (DIVy + 1)) \text{ with } y = P, Q \text{ or } R$$

When the PLL is configured in fractional mode (SH\_REG different from '0'), the DIVN divider must be initialized before enabling the PLLs. However, it is possible to change the value of FRACNx on-the-fly without disturbing the PLL output.

This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

$$F_{VCO} = F_{ref\_ck} \times \left( DIVN + \frac{FRACN}{2^{(13)}} \right)$$

*Note:* For PLL1, DIVP can only take odd values.

The PLLs are disabled by hardware when:

- The system enters Stop or Standby mode.
- An HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock.

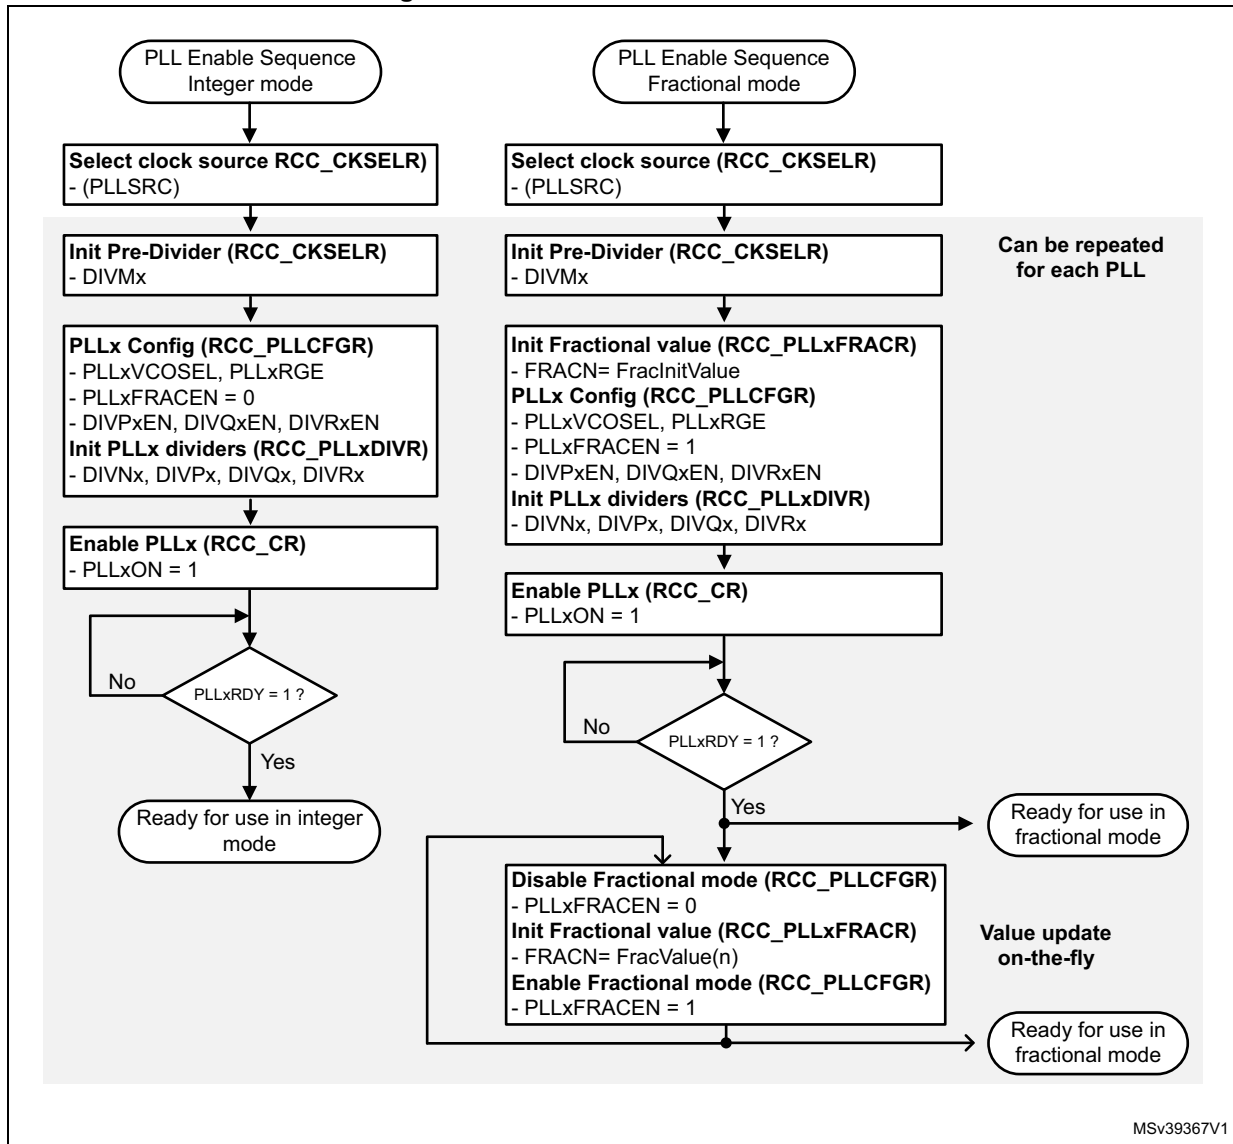

### PLL initialization phase

[Figure 39](#) shows the recommended PLL initialization sequence in integer and fractional mode. The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Initialize the PLLs registers according to the required frequency.
  - Set PLLxFRACEN of *RCC PLLs Configuration Register (RCC\_PLLCFGR)* to '0' for integer mode.
  - For fractional mode, set FRACN to the required initial value (FracInitValue) and then set PLLxFRACEN to '1'.
2. Once the PLLxON bit is set to '1', the user application has to wait until PLLxRDY bit is set to '1'. If the PLLx is in fractional mode, the PLLxFRACEN bit must not be set back to '0' as long as PLLxRDY = '0'.
3. Once the PLLxRDY bit is set to '1', the PLLx is ready to be used.
4. If the application intends to tune the PLLx frequency on-the-fly (possible only in fractional mode), then:
  - a) PLLxFRACEN must be set to '0',  
When PLLxFRACEN = '0', the Sigma-Delta modulator is still operating with the value latched into SH\_REG.
  - b) A new value must be uploaded into PLLxFRACR (FracValue(n)).
  - c) PLLxFRACEN must be set to '1', in order to latch the content of PLLxFRACR into its shadow register.

*Note:* When the PLLxRDY goes to '1', it means that the difference between the PLLx output frequency and the target value is lower than  $\pm 2\%$ .

Figure 39. PLLs Initialization Flowchart

MSV39367V1

## 8.5.6 System clock (sys\_ck)

### System clock selection

After a system reset, the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, it is not possible for the software to disable the selected source via the xxxON bits.

Of course, the system clock can be stopped by the hardware when the System enters Stop or Standby mode.

When the system is running, the user application can select the system clock (**sys\_ck**) among the 4 following sources:

- HSE
- HSI
- CSI
- or pll1\_p\_ck

This function is controlled by programming the [RCC Clock Configuration Register \(RCC\\_CFGR\)](#). A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SWS status bits in the [RCC Clock Configuration Register \(RCC\\_CFGR\)](#) indicate which clock is currently used as system clock. The other status bits in the RCC\_CR register indicate which clock(s) is (are) ready.

### System clock generation

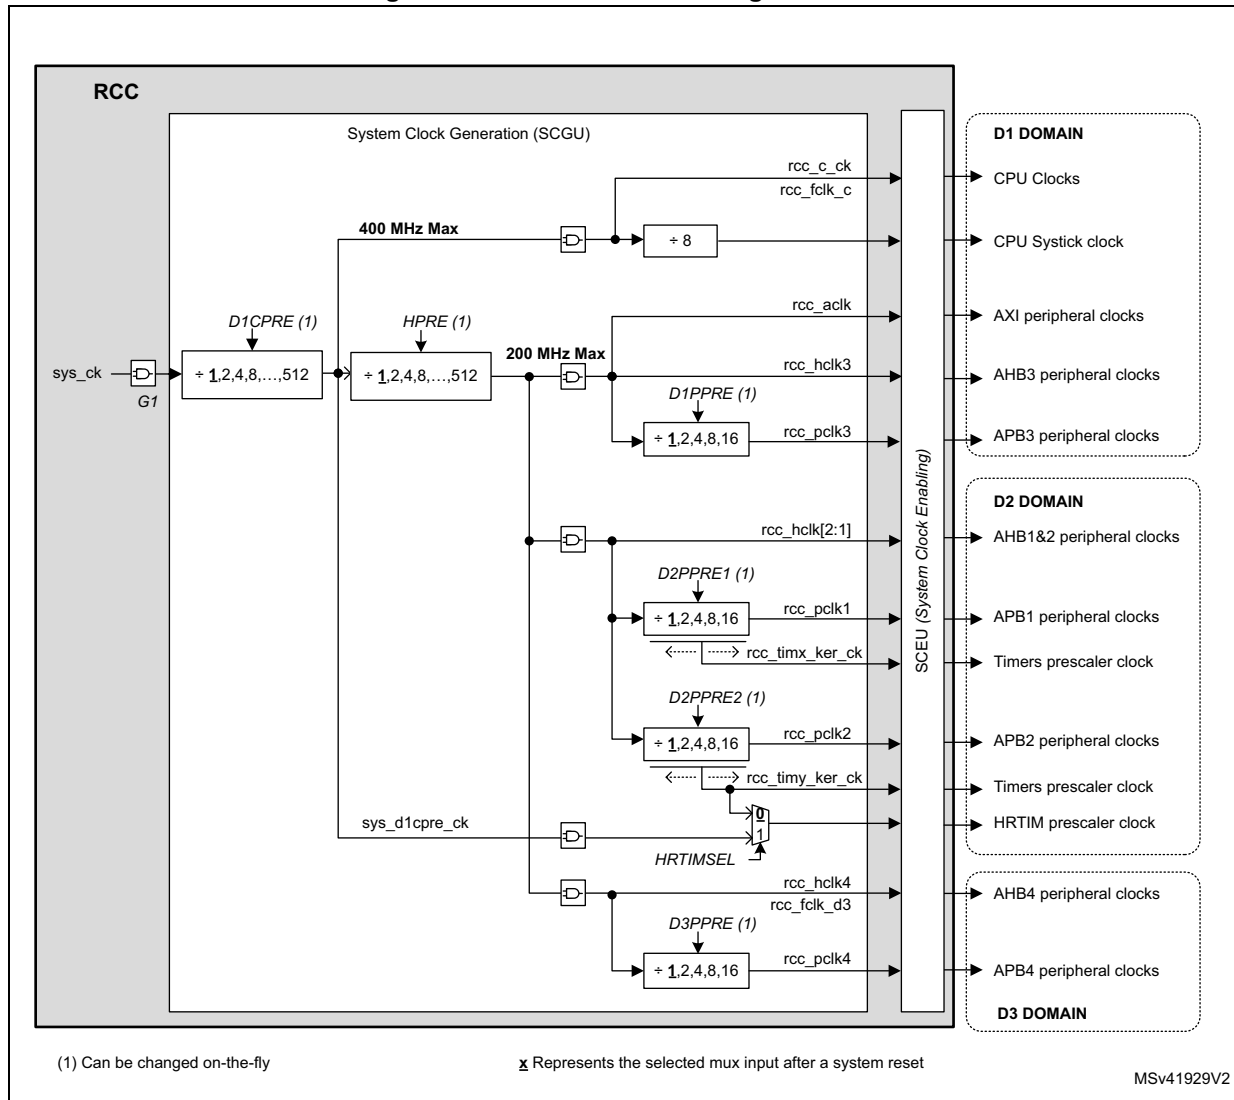

[Figure 40](#) shows a simplified view of the clock distribution for the CPU and busses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simply solution to adapt the busses frequencies to the application needs, thus optimizing the power consumption.

The D1CPRE divider can be used to adjust the CPU clock. However this also impacts the clock frequency of all bus matrix and HRTIM.

In the same way, HPRE divider can be used to adjust the clock for D1 domain bus matrix, but this also impacts the clock frequency of bus matrix of D2 and D3 domains.

Most of the prescalers are controlled via RCC\_D1CFGR, RCC\_D2CFGR and RCC\_D3CFGR registers.

Figure 40. Core and bus clock generation

This block also provides the clock for the timers (**rcc\_timx\_ker\_ck** and **rcc\_timy\_ker\_ck**). The frequency of the timers clock depends on the APB prescaler corresponding to the bus to which the timer is connected, and on TIMPRE bit. [Table 48](#) shows how to select the timer clock frequency.

Table 48. Ratio between clock timer and pclk

D2PPRE1 (1) D2PPRE2	TIMPRE (2)		$F_{rcc\_timx\_ker\_ck}$ $F_{rcc\_timy\_ker\_ck}$	$F_{rcc\_pclk1}$ $F_{rcc\_pclk2}$	Comments
0xx	0	→	$F_{rcc\_hclk1}$	$F_{rcc\_hclk1}$	The timer clock is equal to the bus clock.
100	0	→	$F_{rcc\_hclk1}$	$F_{rcc\_hclk1} / 2$	The timer clock is twice as fast as the bus clock.
101	0	→	$F_{rcc\_hclk1} / 2$	$F_{rcc\_hclk1} / 4$	
110	0	→	$F_{rcc\_hclk1} / 4$	$F_{rcc\_hclk1} / 8$	
111	0	→	$F_{rcc\_hclk1} / 8$	$F_{rcc\_hclk1} / 16$	

**Table 48. Ratio between clock timer and pclk (continued)**

D2PPRE1 (1) D2PPRE2	TIMPRE (2)		F <sub>rcc_timx_ker_ck</sub> F <sub>rcc_timy_ker_ck</sub>	F <sub>rcc_pclk1</sub> F <sub>rcc_pclk2</sub>	Comments
0xx	1	→	F <sub>rcc_hclk1</sub>	F <sub>rcc_hclk1</sub>	The timer clock is equal to the bus clock.
100	1	→	F <sub>rcc_hclk1</sub>	F <sub>rcc_hclk1</sub> / 2	The timer clock is twice as fast as the bus clock.
101	1	→	F <sub>rcc_hclk1</sub>	F <sub>rcc_hclk1</sub> / 4	The timer clock is 4 times faster than the bus clock.
110	1	→	F <sub>rcc_hclk1</sub> / 2	F <sub>rcc_hclk1</sub> / 8	
111	1	→	F <sub>rcc_hclk1</sub> / 4	F <sub>rcc_hclk1</sub> / 16	

1. D2PPRE1 and D2PPRE2 belong to [RCC Domain 2 Clock Configuration Register \(RCC\\_D2CFGR\)](#).
2. TIMPRE belongs to [RCC Clock Configuration Register \(RCC\\_CFGR\)](#).

### 8.5.7 Handling clock generators in Stop and Standby mode

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped as well as the following clock sources:

- CSI, HSI (depending on HSIKERON, and CSIKERON bits)
- HSE
- PLL1, PLL2 and PLL3
- HSI48

The content of the RCC registers is not altered except for PLL1ON, PLL2ON, PLL3ON HSEON and HSI48ON which are set to '0'.

#### Exiting Stop mode

When the microcontroller exits system Stop mode via a wake-up event, the application can select which oscillator (HSI and/or CSI) will be used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

All these bits belong to the [RCC Clock Configuration Register \(RCC\\_CFGR\)](#). [Table 49](#) gives a detailed description of their behavior.

**Table 49. STOPWUCK and STOPKERWUCK description**

STOPWUCK	STOPKERWUCK		Activated oscillator when the system exits Stop mode	Distributed clocks when System exits Stop mode	
				System Clock	Kernel Clock
0	0	→	HSI	HSI	HSI
	1	→	HSI and CSI		HSI and/or CSI
1	0	→		CSI	CSI
	1	→	CSI		

**During Stop mode**

There are two specific cases where the HSI or CSI can be enabled during system Stop mode:

- When a dedicated peripheral requests the kernel clock:  
In this case the peripheral will receive the HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- When the bits HSIKERON or CSIKERON are set:  
In this case the HSI and CSI are kept running during Stop mode but the outputs are gated. In that way, the clock will be available immediately when the system exits Stop mode or when a peripheral requests the kernel clock (see [Table 50](#) for details).

HSIKERON and CSIKERON bits belong to [RCC Source Control Register \(RCC\\_CR\)](#). [Table 50](#) gives a detailed description of their behavior.

**Table 50. HSIKERON and CSIKERON behavior**

HSIKERON (CSIKERON)		HSI (CSI) state during Stop mode	HSI (CSI) Setting time
0	→	OFF	$t_{su(HSI)} (t_{su(CSI)})^{(1)}$
1	→	Running & Gated	Immediate

1.  $t_{su(HSI)}$  and  $t_{su(CSI)}$  are the startup times of the HSI and CSI oscillators (see refer to the product datasheet for the values of these parameters).

When the microcontroller exists system Standby mode, the HSI is selected as system and kernel clock, the RCC registers are reset to their initial values except for the RCC\_RSR (or RCC\_C1\_RSR) and RCC\_BDCR registers.

Note as well that the HSI and CSI outputs provide two clock paths (see [Figure 36](#)):

- one path for the system clock (**hsi\_ck** or **csi\_ck**)
- one path for the peripheral kernel clock (**hsi\_ker\_ck** or **csi\_ker\_ck**).

When a peripheral requests the kernel clock in system Stop mode, only the path providing the **hsi\_ker\_ck** or **csi\_ker\_ck** is activated.

**Caution:** It is not guaranteed that the CPU will get automatically the same clock frequencies when leaving CStop mode: this mainly depends on the System state. For example If the CPU goes to CStop, while the D3 domain is kept in CRun, when the CPU exits from CStop, the clock settings remain unchanged. If the D3 domain goes to CStop while the CPU is also in CStop, then when the CPU exits from CStop, the CPU will operate with HSI or CSI when it left the CStop mode.

### 8.5.8 Kernel clock selection

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (**ckg\_bus\_perx** clock)
- and a clock domain generally synchronous with the peripheral (kernel clock).

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral.

As a consequence, the user application can change the bus frequency without reprogramming the peripherals. As an example an on-going transfer with UART will not be disturbed if its APB clock is changed on-the-fly.

[Table 51](#) shows the kernel clock that the RCC can deliver to the peripherals. Each row of [Table 51](#) represents a MUX and the peripherals connected to its output. The columns starting from number 4 represents the clock sources. Column 3 gives the maximum allowed frequency at each MUX output. It is up to the user to respect these requirements.

Table 51. Kernel clock distribution overview

Peripherals	Clock mux control bits	Max. allowed freq. [MHz]	Domain	Clock Sources

1. The bus clocks are the bus interface clocks to which the peripherals are connected, it can be APB, AHB or AXI clocks.
2. The per\_ck clock could be hse\_ck, hsi\_ker\_ck or csi\_ker\_ck according to CKPERSEL selection.
3. Clock CSI divided by 122.
4. With a duty cycle close to 50%, meaning that DIV[P/Q/R]x values shall be even. For SDMMCx, the duty cycle shall be 50% when supporting DDR.
5. Clock HSE divided by RTCPRE.

Figure 41 to Figure 50 provide a more detailed description of kernel clock distribution. To simplify the drawings, the bus interface clocks (pclk, hclk) are not represented, even if they are gated with enable signals. Refer to Section 8.5.11: Peripheral clock gating control for more details.

To reduce the amount of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

### Peripherals dedicated to audio applications

The audio peripherals generally need specific accurate frequencies, except for SPDIFRX. As shown in Figure 41, the kernel clock of the SAI4s or SPI(I2S)s can be generated by:

- The PLL1 when the amount of active PLLs has to be reduced
- The PLL2 or 3 for optimal flexibility in frequency generation
- HSE, HSI or CSI for use-cases where the current consumption is critical
- I2S\_CKIN when an external clock reference need to be used.

*Note:* The SPDIFRX does not require a specific frequency, but only a kernel clock frequency high enough to make the peripheral work properly. Refer to the SPDIFRX description for more details.

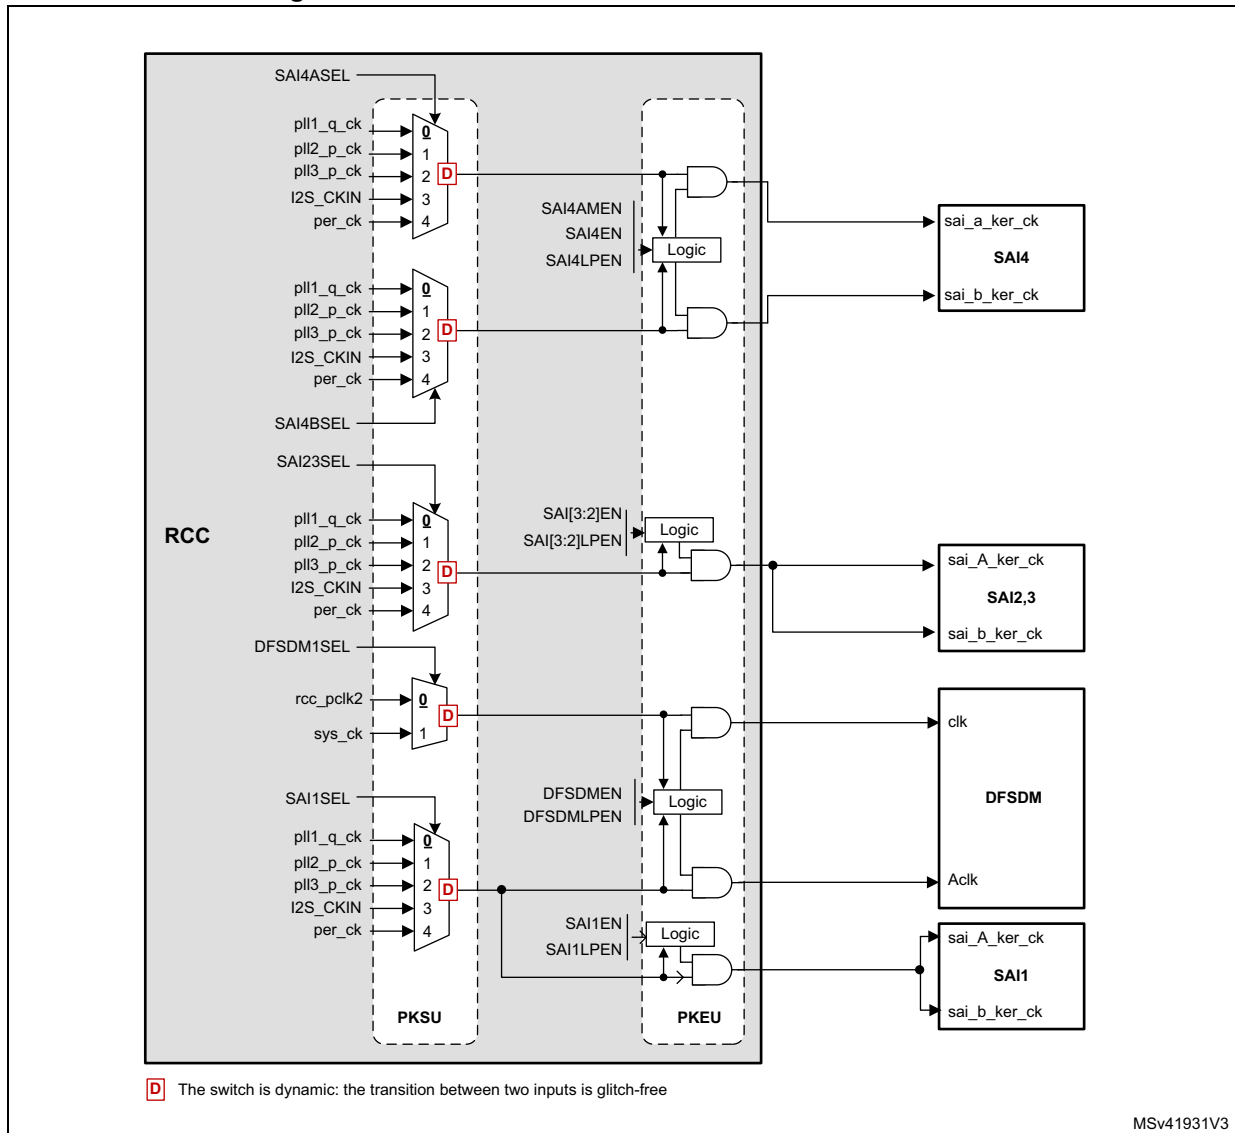

DFSDM1 can use the same clock as SAI1A. This is useful when DFSDM1 is used for audio applications.

To improve the flexibility, SAI4 can use different clock for each sub-block.

The SPI/I2S1, 2, and 3 share the same kernel clock source (see Figure 42).

Figure 41. Kernel clock distribution for SAIs and DFSDM

2. This figure does not show the connection of the bus interface clock to the peripherals. For details on each enable cell, please refer to [Section 8.5.11: Peripheral clock gating control](#).

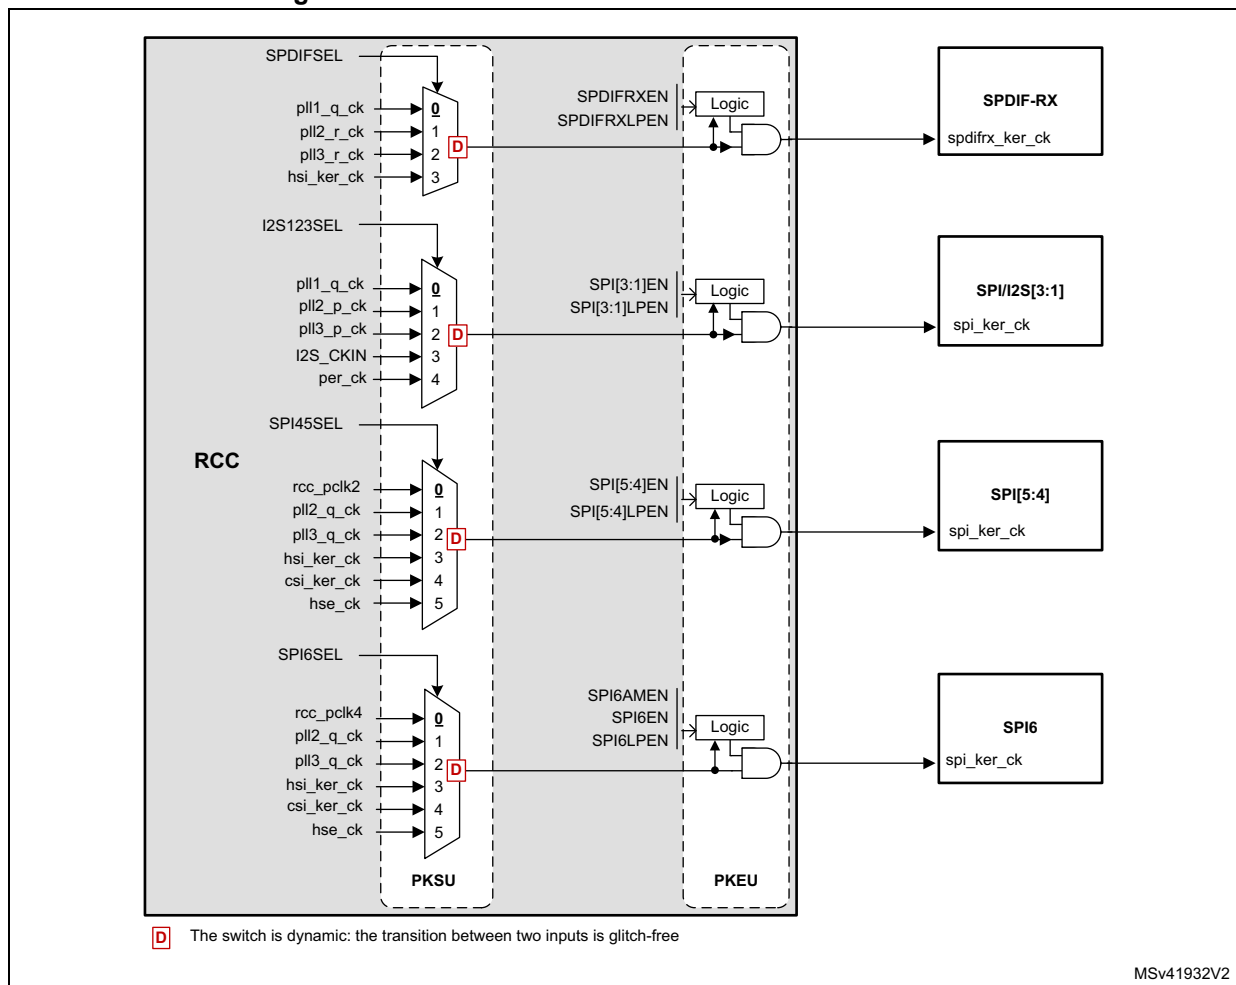

### Peripherals dedicated to control and data transfer

Peripherals such as SPIs, I2Cs, UARTs do not need a specific kernel clock frequency but a clock fast enough to generate the correct baud rate, or the required bit clock on the serial interface. For that purpose the source can be selected among:

- PLL1 when the amount of active PLLs has to be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI for low-power use-cases or when the peripheral has to quickly wake up from Stop mode (i.e. UART, I2C...).

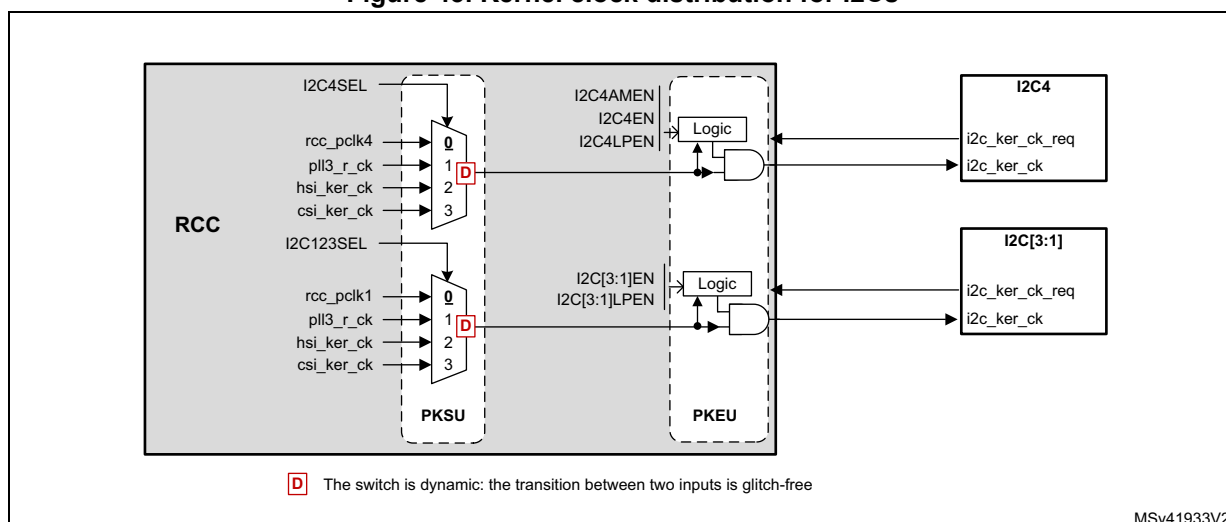

Note: UARTs also need the LSE clock when high baud rates are not required.

### RTC/AWU clock

The **rtc\_ck** clock source can be:

- the **hse\_1M\_ck** (**hse\_ck** divided by a programmable prescaler)
- the **lse\_ck**
- or the **lsi\_ck** clock

The source clock is selected by programming the RTCSEL[1:0] bits in the [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#) and the RTCPRE[5:0] bits in the [RCC Clock Configuration Register \(RCC\\_CFGR\)](#).

This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as RTC clock, the RTC will work normally even if the backup or the  $V_{DD}$  supply disappears.

The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

- If LSE is selected as RTC clock, the RTC continues working even if the  $V_{DD}$  supply is switched OFF, provided the  $V_{BAT}$  supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the  $V_{DD}$  supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the  $V_{DD}$  supply is powered off or if the  $V_{CORE}$  supply is powered off.

The `rtc_ck` clock is enabled through RTCEN bit located in the [RCC Backup Domain Control Register \(RCC\\_BDCR\)](#).

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC\_APB4ENR/LPENR registers.

**Note:** *To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ( $F_{APB} < 7 \times F_{RTCLK}$ ), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC\_TR gives the same result than the first one. Otherwise a third read access must be performed.*

### Watchdog clocks

The RCC provides the clock for the four watchdog blocks available on the circuit. The independent watchdog (IWDG1) is connected to the LSI. The window watchdog (WWDG1) are connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDGs.

**Caution:** Before enabling the WWDG1, the application must set the WW1RSC bit to '1'. If the WW1RSC remains to '0', when the WWDG1 is enabled, its the behavior is not guaranteed. The WW1RSC bit is located in [RCC Global Control Register \(RCC\\_GCR\)](#).

### Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI or CSI with the LSE

The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio): the precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see [RCC Internal Clock Source Calibration Register \(RCC\\_ICSCR\)](#)). When

the HSI or CSI are used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

- Calibrating the LSI with the HSI

The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultralow power LSI oscillator has a large manufacturing process deviation. By measuring it versus the HSI clock source, it is possible to determine its frequency with the precision of the HSI. The measured value can be used to have more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy.

### 8.5.9 General clock concept overview

The RCC handles the distribution of the CPU, bus interface and peripheral clocks for the system (D1, D2 and D3 domains), according to the operating mode of each function (refer to [Section 8.5.1: Clock naming convention](#) for details on clock definitions).

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock. Prior to use a peripheral, the CPU has to enable it (by setting PERxEN to '1'), and define if this peripheral remains active in CSleep mode (by setting PERxLPEN to '1'). This is called 'allocation' of a peripheral to the CPU (refer to [Section 8.5.10: Peripheral allocation](#) for more details).

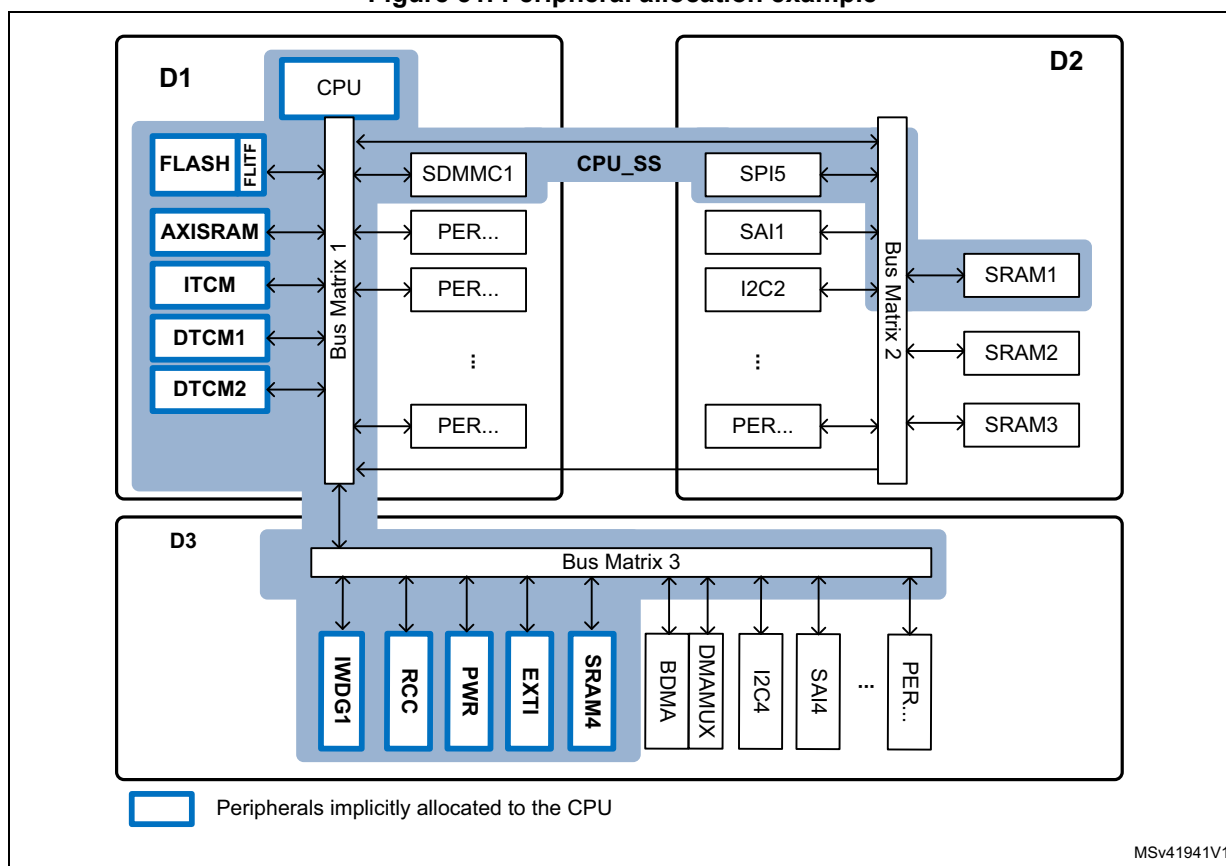

The peripheral allocation is used by the RCC to automatically control the clock gating according to the CPU and domain modes, and by the PWR to control the supply voltages of D1, D2 and D3 domains.

[Figure 51](#) gives an example of peripheral allocation:

- The CPU enabled SDMMC1, SPI5 and SRAM1, AXISRAM, ITCM, DTCM1, DTCM2 and SRAM4 are implicitly allocated to the CPU. The group composed of the CPU, bus matrix 1/2/3 and allocated peripherals makes up a sub-system (CPU\_SS).

*Note:* The FLASH, AXISRAM, ITCM, DTCM1, DTCM2, SRAM4, IWGD1, IWGD2, PWR, EXTI and RCC are common resources and are implicitly allocated to the CPU.

Figure 51. Peripheral allocation example

When the CPU enters CStop mode, the RCC automatically disables the bus interface and kernel clocks of all the peripherals of the CPU\_SS as well as the CPU clock. The PLLs, if enabled, are not disabled by the RCC since D3 is still running.

The D3 domain can be kept in DRun mode while the CPU is in CStop mode and D1 and D2 domains are in DStop or DStandby mode. This is done by setting RUN\_D3 bit in PWR\_CPUCR registers.

- If RUN\_D3 is set to '1', then D3 is maintained in DRun mode, independently from the CPU modes (see [PWR CPU control register \(PWR\\_CPUCR\)](#)).
- If RUN\_D3 is set to '0', then D3 domain enters DStop or DStandby mode when the CPU enters CStop mode (see [Table 52](#)).

Note that the CPU can control if D1, D2 or D3 domains are allowed to enter in DStandby when conditions are met, via bits PDDS\_D1, PDDS\_D2 and PDDS\_D3 of [PWR CPU control register \(PWR\\_CPUCR\)](#).

A wakeup event will be able to exit D1, D2 and D3 domains from DStandby or DStop mode.

In addition, more autonomy can be given to some peripherals located into D3 domain (refer to [Section : D3 domain Autonomous mode](#) for details).

### D3 domain Autonomous mode

The Autonomous mode allows to deliver the peripheral clocks to peripherals located in D3, even if the CPU is in CStop mode. When a peripheral has its autonomous bit enabled, it receives its peripheral clocks according to D3 domain state, if the CPU is in CStop mode:

- If the D3 domain is in DRun mode, peripherals with Autonomous mode activated receive their peripheral clocks,
- If the D3 domain is in DStop mode, no peripheral clock is provided.

The Autonomous mode does not prevent the D3 domain to enter DStop or DStandby mode.

The autonomous bits are located in [RCC D3 Autonomous mode Register \(RCC\\_D3AMR\)](#).

For example, the CPU can enter CStop mode, while the SAI4 is filling the SRAM4 with data received from an external device via BDMA. When the amount of received data is reached, the CPU can be activated by a wakeup event. This can be done by setting the SAI4, the BDMA, and SRAM4 in Autonomous mode, while keeping D3 in DRun mode (RUN\_D3 set to '1'). In this example, the RCC does not switch off the PLLs as the D3 domain is always in DRun mode.

It is possible to go a step further with power consumption reduction by combining the Autonomous mode with the capability of some peripherals (UARTs, I2Cs) to request the kernel clock on their own, without waking-up the CPU. For example, if the system is expecting messages via I2C4, the whole system can be put in Stop mode. When the I2C4 peripheral detects a START bit, it will generate a "kernel clock request". This request enables the HSI or CSI, and a kernel clock is provided only to the requester (in our example the I2C4). The I2C4 then decodes the incoming message. Several cases are then possible:

- If the device address of the message does not match, then I2C4 releases its "kernel clock request" until a new START condition is detected.
- If the device address of the incoming message matches, it has to be stored into D3 local memory. I2C4 is able to generate a wakeup event on address match to switch the D3 domain to DRun mode. The message is then transferred into memory via BDMA, and the D3 domain go back to DStop mode without any CPU activation. Note that if the amount of data transferred into memory reached the transfer count, the BDMA can also generate an interrupt to wake-up the CPU.
- If the device address of the incoming message matches and the peripheral is setup to wake up the CPU, then I2C4 generates a wakeup event to activate the CPU.

Please refer to the description of EXTI block in order see which peripheral is able to perform a wake-up event to which domain.

### Memory handling

The CPU can access all the memory areas available in the product:

- AXISRAM, ITCM, DTCM1, DTCM2 and FLASH,
- SRAM1, SRAM2 and SRAM3,
- SRAM4 and BKPRAM.

As shown in [Figure 51](#), FLASH, AXISRAM, SRAM4, ITCM, DTCM1 and DTCM2 are implicitly allocated to the CPU. As a result, there is no enable bit allowing the CPU to allocate these memories.

If the CPU wants to use memories located into D2 domain (SRAM1, SRAM2 and SRAM3), it has to enable them.

The BKPRAM has a dedicated enable in order to gate the bus interface clock. The CPU needs to enable the BKPRAM prior to use it.

*Note:* The memory interface clocks (Flash and RAM interfaces) can be stopped by software during CSleep mode (via DxSRAMyLPEN bits).

Refer to [Peripheral clock gating control](#) and [CPU and bus matrix clock gating control](#) sections for details on clock enabling.

### System states overview

Table 52 gives an overview of the system states with respect to the D1, D2 and D3 domain modes.

- The system remains in Run mode as long as D3 is in DRun mode. Several sub-states of system Run exist that are not detailed here (refer [Power control \(PWR\)](#) for more information).
- When the D1 domain is in DRun, the D2 domain can be in DRun, DStop or DStandby. When the D1 domain is in DStop or DStandby, the D2 domain can no longer remain in DRun it will switch to DStop or DStandby according to PDDS\_D2 bit.
- D3 can run while D1 and D2 are in DStop/DStandby mode thanks to RUN\_D3 bits of PWR\_CPUCR registers or when D3 is in Autonomous mode.
- The system remains in Stop mode as long as D3 is in DStop mode. This means implicitly that D1 and D2 are in DStop or DStandby. As soon as D1 or D2 exits DStop or DStandby, D3 switches to DRun mode.
- The system remains in Standby mode as long as D1, D2 and D3 are in DStandby.
- Domain states versus CPU states:
  - When the D1 domain is in DRun mode, it means that its bus matrix is clocked, and the CPU is in CRun mode.
  - When the D2 domain is in DRun mode, it means that its bus matrix is clocked, and the CPU is in CRun mode with at least a peripheral of D2 domain allocated.
  - When the D1 domain is in DStop mode it means that its bus matrix is no longer clocked, and the CPU is in CStop mode.
  - When the D2 domain is in DStop mode it means that its bus matrix is no longer clocked. This situation happens when:
    - the CPU did not allocate peripherals of D2 domain,
    - the CPU allocated peripherals of D2 domain, but the CPU is in CStop or CStandby,
  - When a domain is in DStandby mode, it means that the domain including its CPU are powered down.

**Table 52. System states overview**

System State	D1 State	D2 State	D3 State
Run	DRun	DRun/DStop/DStandby	DRun
	DStop/DStandby	DStop/DStandby	
Stop	DStop/DStandby	DStop/ DStandby	DStop
Standby	DStandby	DStandby	DStandby

### 8.5.10 Peripheral allocation

The CPU can allocate a peripheral and hence control its kernel and bus interface clock.

The CPU can allocate a peripheral by setting the dedicated PERxEN bit located into:

- RCC\_xxxxENR registers or
- RCC\_C1\_xxxxENR registers.

The CPU can control the peripheral clocks gating when it is in CSleep mode via the PERxLPEN bits located into:

- RCC\_xxxxLPENR registers or
- RCC\_C1\_xxxxLPENR registers.

Refer to [Section 8.7.1: Register mapping overview](#) for additional information.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. However they are also used to link peripherals to the CPU (CPU sub-system). In this way, the hardware is able to safely gate the peripheral clocks and bus matrix clocks according to CPU states. The PWR block also uses this information to control properly the domain states.

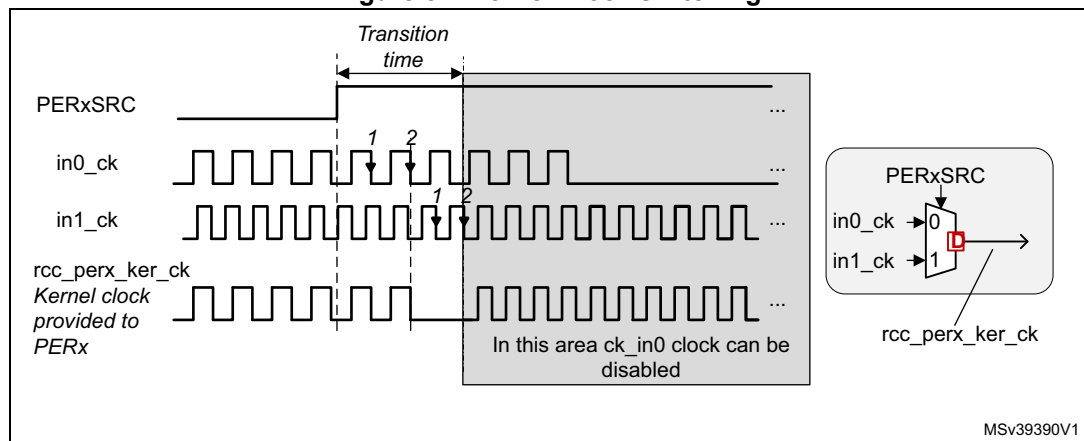

#### Clock switches and gating

- Clock switching delays

The input selected by the kernel clock switches can be changed dynamically without generating spurs or timing violation. As a consequence, switching from the original to the new input can only be performed if a clock is present on both inputs. If it not the case, no clock will be provided to the peripheral. To recover from this situation, the user has to provide a valid clock to both inputs.

During the transition from one input to another, the kernel clock provided to the peripheral will be gated, in the worst case, during 2 clock cycles of the previously selected clock and 2 clock cycles of the new selected clock. As shown in [Figure 52](#), both input clocks shall be present during transition time.

**Figure 52. Kernel Clock switching**

- Clock enabling delays

In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock, in order to avoid generation of spurs.

- A maximum delay of two periods of the enabled clock may occur between the enable command and the first rising edge of the clock. The enable command can be the rising edge of the PERxEN bits of RCC\_xxxxENR registers, or a kernel clock request asserted by a peripheral.
- A maximum delay of 1.5 periods of the disabled clock may occur between the disable command and the last falling edge of the clock. The disable command can be the falling edge of the PERxEN bits of RCC\_xxxxENR registers, or a kernel clock request released by a peripheral.

*Note:* Both the kernel clock and the bus interface clock are affected by this re-synchronization delay.

In addition, the clock enabling delay may strongly increase if the application is enabling for the first time a peripheral which is not located into the same domain. This is due to the fact that the domain where the peripheral is located could be in DStop or DStandby mode. The domain must be switched to DRun mode before the application can use this peripheral.

As an example, if the CPU enables a peripheral located in the D2 domain while the D2 domain is in DStop/DStandby mode, then the power controller (PWR) has first to provide a supply voltage to D2, then the RCC has to wait for an acknowledge from the PWR before enabling the clocks of the D2 domain. To handle properly this situation the RCC and the PWR blocks feature four flags:

- D1CKRDY/D2CKRDY located in [RCC Source Control Register \(RCC\\_CR\)](#)
- SBF\_D1 and SBF\_D2 located in [PWR CPU control register \(PWR\\_CPUCR\)](#).

The following sequence can be followed to avoid this issue:

- Enable the peripheral clocks (i.e. allocate the peripheral) by writing the corresponding PERxEN bit to '1' in the RCC\_xxxxENR register,
- Read back the RCC\_xxxxENR register to make sure that the previous write operation is not pending into a write buffer.
- If the peripheral is located in a different domain, perform the two next steps:  
Read DxCKRDY until it is set to '1'.  
Write SBF\_Dx to zero and read-back the value, in order to check if the domain where the peripheral is located is still in DStandby. If the corresponding bit is read at '1', it means that the domain is still in DStandby. Repeat this operation until SBF\_Dx is equal to '0', then continue the other steps.
- Perform a dummy read operation into a register of the enabled peripheral. This operation will take at least 2 clock cycles, which is equal to the max delay of the enable command.
- The peripheral can then be used.

*Note:* When the bus interface clock is not active, read or write accesses to the peripheral registers are not supported. A read access will return invalid data. A write access will be ignored and will not create any bus errors.

### 8.5.11 Peripheral clock gating control

As mentioned previously, each peripheral requires a bus interface clock, named **rcc\_perx\_bus\_ck** (for peripheral 'x'). This clock can be an APB, AHB or AXI clock, according to which bus the peripheral is connected.

The clocks used as bus interface for peripherals located in D1 domain, could be **rcc\_aclk**, **rcc\_hclk3** or **rcc\_pclk3**, depending on the bus connected to each peripheral. For simplicity sake, these clocks are named **rcc\_bus\_d1\_ck**.

In the same way, the signal named **rcc\_bus\_d2\_ck** represents **rcc\_hclk1**, **rcc\_hclk2**, **rcc\_pclk1** or **rcc\_pclk2**, depending on the bus connected to each peripheral of D2 domain.

Similarly, the signal **rcc\_bus\_d3\_ck** represents **rcc\_hclk4** or **rcc\_pclk4** for peripherals located in D3.

Some peripherals (SAI, UART...) also require a dedicated clock for their communication interface. This clock is generally asynchronous with respect to the bus interface clock. It is named kernel clock (**perx\_ker\_ckreq**). Both clocks can be gated according to several conditions detailed hereafter.

As shown in [Figure 53](#), enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits  
PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to '1' via RCC\_C1\_xxxxENR or RCC\_xxxxENR registers.
- PERxAMEN bits  
The PERxAMEN bits are belong to [RCC D3 Autonomous mode Register \(RCC\\_D3AMR\)](#).
- CPU state (**c\_sleep** and **c\_deepsleep** signals)
- D3 domain state (**d3\_deepsleep** signal)
- The kernel clock request (**perx\_ker\_ckreq**) of the peripheral itself, when the feature is available.

Refer to [Section 8.5.10: Peripheral allocation](#) for more details.

Figure 53. Peripheral kernel clock enable logic details

Table 53 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in D1 or D2 domain and allocated by the CPU.

**Table 53. Peripheral clock enabling for D1 and D2 peripherals**

PERxEN	PERxLPEN	PERxSRC	perx_ker_ckreq	CPU State	rcc_perx_ker_c_en	rcc_perx_bus_d1_en	Comments
0	X	X	X	X	0	0	No clock provided to the peripheral, because PERxEN='0'
1	X	X	X	CRun	1	1	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in CRun, and PERxEN='1'
1	0	X	X	CSleep	0	0	No clock provided to the peripheral, because the CPU is in CSleep, and PERxLPEN='0'
1	1	X	X		1	1	Kernel and bus interface clocks are provided to the peripheral, because CPU is in CSleep, and PERxLPEN='1'
1	0	X	X	CStop	0	0	No clock provided to the peripheral because the PERxLPEN bit is set to '0'.
1	1	no lsi_ck and no lse_ck and no hsi_ker_ck and no csi_ker_ck	X		0	0	No clock provided to the peripheral because CPU is in CStop and lse_ck or lsi_ck or hsi_ker_ck or csi_ker_ck are not selected.
1	1	lsi_ck or lse_ck	X		1 (1)	0	Kernel clock is provided to the peripheral because PERxEN = PERxLPEN='1' and lsi_ck or lse_ck are selected. The bus interface clock is no provided as the CPU is in CStop
1	1	hsi_ker_ck or csi_ker_ck	1		1	0	Kernel clock is provided to the peripheral because req_ker_perx = '1', and PERxEN = PERxLPEN='1' and hsi_ker_ck or csi_ker_ck are selected. The bus interface clock is no provided as the CPU is in CStop
1	1	hsi_ker_ck or csi_ker_ck	0		0	0	No clock provided to the peripheral because CPU is in CStop, and no kernel clock request pending

1. For RNG block, the kernel clock is not delivered if the CPU to which it is allocated is in CStop mode, even if the clock selected is lsi\_ck or lse\_ck.

As a summary, we can state that the kernel clock is provided to the peripherals located on domains D1 and D2 when the following conditions are met:

1. The CPU is in CRun mode, and the peripheral is allocated.
2. The CPU is in CSleep mode, and the peripheral is allocated with PERxLPEN = '1'.
3. The CPU is in CStop mode, and the peripheral is allocated with PERxLPEN = '1', and the peripheral generates a kernel clock request, and the selected clock is **hsi\_ker\_ck** or **csi\_ker\_ck**.
4. The CPU is in CStop mode, and the peripheral is allocated with PERxLPEN = '1', and the kernel source clock of the peripheral is **lse\_ck** or **lsi\_ck**.

The bus interface clock will be provided to the peripherals only when conditions 1 or 2 are met.

Table 54 gives a detailed description of the enabling logic of the kernel clock for all peripherals located in D3.

**Table 54. Peripheral clock enabling for D3 peripherals**

PERxEN	PERxLPEN	PERxAMEN	PERxSRC	perx_ker_ckreq	CPU State	D3 State	rcc_perx_ker_d3_en	rcc_perx_bus_d3_en	Comments
0	X	X	X	X	Any	Any	0	0	No clock provided to the peripheral, as PERxEN='0'
1	X	X	X	X	CRun	DRun	1	1	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in CRun, and PERxEN='1'
1	0	X	X	X	CSleep		0	0	No clock provided to the peripheral, because the CPU is in CSleep, and PERxLPEN='0'
1	1	X	X	X			1	1	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in CSleep, and PERxLPEN='1'
1	X	0	X	X	CStop	DRun	0	0	As the CPU is in CStop, and PERxEN='1', then the kernel clock gating depends on D3 state and PERxAMEN bits. No clock provided to the peripheral because PERxAMEN = '0'.
1	X	1	X	X			1	1	The kernel and bus interface clocks are provided because even if the CPU is in CStop mode, D3 is in DRun mode, with PERxEN and PERxAMEN bits set to '1'.
1	X	1	not lse_ck and not lsi_ck	0		DStop	0	0	No clock provided to the peripheral, because D3 is in DStop, req_ker_perx = '0', and lse_ck or lsi_ck are not selected.

Table 54. Peripheral clock enabling for D3 peripherals (continued)

PERxEN	PERxLPEN	PERxAMEN	PERxSRC	perx_ker_ckreq	CPU State	D3 State	rcc_perx_ker_d3_en	rcc_perx_bus_d3_en	Comments
1	X	1	not hsi_ker_ck and not csi_ker_ck and not lse_ck and not lsi_ck	1	CStop	DStop	0	0	No clock provided to the peripheral, because even if req_ker_perx = '0', lse_ck or lsi_ck or hsi_ker_ck or csi_ker_ck are not selected.
1	X	1	hsi_ker_ck or csi_ker_ck	1			1	0	Kernel clock is provided to the peripheral because req_ker_perx = '1', and PERxEN = PERxAMEN='1', and the selected clock is hsi_ker_ck or csi_ker_ck. The bus interface clock is not provided as D3 is in DStop.
1	X	1	lse_ck or lsi_ck	X			1	0	Kernel clock is provided to the peripheral because PERxEN = PERxAMEN='1' and lse_ck or lsi_ck are selected, while D3 is in STOP. The bus interface clock is not provided as D3 is in DSTOP.

As a summary, we can state that the kernel clock is provided to the peripherals of D3 if the following conditions are met:

1. The CPU is in CRun mode, and the peripheral is allocated.
2. The CPU is in CSleep mode, and the peripheral is allocated with PERxLPEN = '1'.
3. The CPU is in CStop mode, and the peripheral is allocated and D3 domain is in DRun mode with PERxAMEN = '1'.
4. The CPU is in CStop mode, and the peripheral is allocated, and D3 domain is in DStop mode with PERxAMEN = '1', and the peripheral is generating a kernel clock request and the kernel clock source is hsi\_ker\_ck or csi\_ker\_ck.
5. The CPU is in CStop mode, and the peripheral is allocated, and D3 domain is in DStop mode with PERxAMEN = '1', and the kernel clock source of the peripheral is lse\_ck or lsi\_ck.

The bus interface clock will be provided to the peripherals only when condition 1, 2 or 3 is met.

*Note:* When they are set to '1', the autonomous bits indicate that the associated peripheral will receive a kernel clock according to D3 state, and not according to the mode of the CPU. Only I2C, U(S)ART and LPUART peripherals are able to request the kernel clock. This feature gives to the peripheral the capability to transfer data with an optimal power consumption.

The autonomous bits dedicated to some peripherals located in D3 domain allow the data transfer with external devices without activating the CPU.

In order for the LPTIMER to operate with **Ise\_ck** or **Isi\_ck** when the circuit is in Stop mode, the user application has to select the **Isi\_ck** or **Ise\_ck** input via LPTIMxSEL fields, and set bit LPTIMxAMEN and LPTIMxLPEN to '1'.

## 8.5.12 CPU and bus matrix clock gating control

For each domain it is possible to control the activation/deactivation of the CPU clock and bus matrix clock.

For information about convention naming, refer to [Section 8.5.11: Peripheral clock gating control](#).

The clocks of the CPU, AHB & AXI bridges and APB busses are enabled according to the rules hereafter:

- The CPU clock **rcc\_c\_ck** is enabled when the CPU is in CRun mode.
- The AXI bridge clock is enabled when the CPU is in CRun mode.
- The D2 domain AHB bridges clocks are enabled when:
  - The CPU is in CRun or,
  - If the CPU is in CSleep with at least a peripheral (master) connected to this bus having both its PERxEN and PERxLPEN set to '1' or,
  - If the CPU is in CSleep with at least an APB bus having its clock enabled.
- The D3 domain AHB bridge clock is enabled when:
  - The CPU is in CRun or CSleep mode or,
  - When the RUN\_D3 bit is set to '1', independently of CPU modes or,
  - When the **d3\_deepsleep** signal is inactive ('0'), independently of CPU modes.
- The APB1,2,3 busses are enabled when:
  - The CPU is in CRun or,
  - If the CPU is in CSleep with at least a peripheral connected to this bus having both its PERxEN and PERxLPEN set to '1'.
- The APB4 bus is enabled when: the D3 domain is in DRun.

As shown in the [Figure 54](#), the enabling of the core and bus clock of each domain depends on several input signals:

- **c\_sleep** and **c\_deepsleep** signals from the CPU,
- **d3\_sleepdeep** signal,
- RCC\_xxxxENR.PERxEN bits of peripherals located on D2 domain

Figure 54. Bus clock enable logic

## 8.6 RCC Interrupts

The RCC provides 3 interrupt lines:

- **rcc\_it**: a general interrupt line, providing events when the PLLs are ready, or when the oscillators are ready.
- **rcc\_hsecss\_it**: an interrupt line dedicated to the failure detection of the HSE Clock Security System.
- **rcc\_lsecss\_it**: an interrupt line dedicated to the failure detection of the LSE Clock Security System.

The interrupt enable is controlled via [RCC Clock Source Interrupt Enable Register \(RCC\\_CIER\)](#), except for the HSE CSS failure. When the HSE CSS feature is enabled, it not possible to mask the interrupt generation.

The interrupt flags can be checked via [RCC Clock Source Interrupt Flag Register \(RCC\\_CIFR\)](#), and those flags can be cleared via [RCC Clock Source Interrupt Clear Register \(RCC\\_CICR\)](#).

*Note:* The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

[Table 55](#) gives a summary of the interrupt sources, and the way to control them.

**Table 55. Interrupt sources and control**

Interrupt Source	Description	Interrupt enable	Action to clear interrupt	Interrupt Line
LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYC to '1'	rcc_it
LSERDYF	LSE ready	LSERDYIE	Set LSERDYC to '1'	
HSIRDYF	HSI ready	HSIRDYIE	Set HSIRDYC to '1'	
HSERDYF	HSE ready	HSERDYIE	Set HSERDYC to '1'	
CSIRDYF	CSI ready	CSIRDYIE	Set CSIRDYC to '1'	
HSI48RDYF	HSI48 ready	HSI48RDYIE	Set HSI48RDYC to '1'	
PLL1RDYF	PLL1 ready	PLL1RDYIE	Set PLL1RDYC to '1'	
PLL2RDYF	PLL2 ready	PLL2RDYIE	Set PLL2RDYC to '1'	
PLL3RDYF	PLL3 ready	PLL3RDYIE	Set PLL3RDYC to '1'	
LSECSSF	LSE Clock security system failure	LSECSSFIE <sup>(1)</sup>	Set LSECSSC to '1'	rcc_lsecss_it
HSECSSF	HSE Clock security system failure	_(2)	Set HSECSSC to '1'	rcc_hsecss_it

1. The security system feature must also be enabled (LSECSSON = '1'), in order to generate interrupts.
2. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = '1').

## 8.7 RCC register description

### 8.7.1 Register mapping overview

Note that the control of PERxEN and PERxLPEN bits can be performed at two different address offset: 0x0D0 and 0x130. So the application can use the registers named:

- RCC\_xxxENR or RCC\_C1\_xxxENR to control the PERxEN bits
- RCC\_xxxLPENR or RCC\_C1\_xxxLPENR to control the PERxLPEN bits
- RCC\_RSR or RCC\_C1\_RSR to control the reset flag status bits.

This feature is provided to insure the compatibility with other products of this family.

Figure 55 shows the RCC mapping overview.

Figure 55. RCC mapping overview

### 8.7.2 RCC Source Control Register (RCC\_CR)

Address offset: 0x000

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PLL3RDY	PLL3ON	PLL2RDY	PLL2ON	PLL1RDY	PLL1ON	Res.	Res.	Res.	Res.	HSECSSON	HSEBYP	HSERDY	HSEON
		r	rw	r	rw	r	rw					rs	rw	r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
D2CKRDY	D1CKRDY	HSI48RDY	HSI48ON	Res.	Res.	CSIKERON	CSIRDY	CSION	Res.	HSIDIVF	HSIDIV[1:0]	HSIRDY	HSIKERON	HSION	
r	r	r	rw			rw	r	rw		r	rw	rw	r	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **PLL3RDY**: PLL3 clock ready flag

Set by hardware to indicate that the PLL3 is locked.  
 0: PLL3 unlocked (default after reset)  
 1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable

Set and cleared by software to enable PLL3.  
 Cleared by hardware when entering Stop or Standby mode.  
 0: PLL3 OFF (default after reset)  
 1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag

Set by hardware to indicate that the PLL2 is locked.  
 0: PLL2 unlocked (default after reset)  
 1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable

Set and cleared by software to enable PLL2.  
 Cleared by hardware when entering Stop or Standby mode.  
 0: PLL2 OFF (default after reset)  
 1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag

Set by hardware to indicate that the PLL1 is locked.  
 0: PLL1 unlocked (default after reset)  
 1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable

Set and cleared by software to enable PLL1.  
 Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to '0', if the PLL1 output is used as the system clock.  
 0: PLL1 OFF (default after reset)  
 1: PLL1 ON

Bits 23:20 Reserved, must be kept at reset value.

**Bit 19 HSECSSON:** HSE Clock Security System enable

Set by software to enable Clock Security System on HSE.

This bit is "set only" (disabled by a system reset or when the system enters in Standby mode).

When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.

0: Clock Security System on HSE OFF (Clock detector OFF) (default after reset)

1: Clock Security System on HSE ON (Clock detector ON if the HSE oscillator is stable, OFF if not).

**Bit 18 HSEBYP:** HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit, to be used by the device.

The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed (default after reset)

1: HSE oscillator bypassed with an external clock

**Bit 17 HSERDY:** HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE clock is not ready (default after reset)

1: HSE clock is ready

**Bit 16 HSEON:** HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE when entering Stop or Standby mode.

This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to '1').

0: HSE is OFF (default after reset)

1: HSE is ON

**Bit 15 D2CKRDY:** D2 domain clocks ready flag

Set by hardware to indicate that the D2 domain clocks are available.

0: D2 domain clocks are not available (default after reset)

1: D2 domain clocks are available

**Bit 14 D1CKRDY:** D1 domain clocks ready flag

Set by hardware to indicate that the D1 domain clocks (CPU, bus and peripheral) are available.

0: D1 domain clocks are not available (default after reset)

1: D1 domain clocks are available

**Bit 13 HSI48RDY:** HSI48 clock ready flag

Set by hardware to indicate that the HSI48 oscillator is stable.

0: HSI48 clock is not ready (default after reset)

1: HSI48 clock is ready

**Bit 12 HSI48ON:** HSI48 clock enable

Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.

0: HSI48 is OFF (default after reset)

1: HSI48 is ON

Bits 11:10 Reserved, must be kept at reset value.

- Bit 9 **CSIKERON**: CSI clock enable in Stop mode  
Set and reset by software to force the CSI to ON, even in Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.  
0: no effect on CSI (default after reset)  
1: CSI is forced to ON even in Stop mode
- Bit 8 **CSIRDY**: CSI clock ready flag  
Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).  
0: CSI clock is not ready (default after reset)  
1: CSI clock is ready
- Bit 7 **CSION**: CSI clock enable  
Set and reset by software to enable/disable CSI clock for system and/or peripheral.  
Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = '1' or STOPKERWUCK = '1'.  
This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to '1').  
0: CSI is OFF (default after reset)  
1: CSI is ON
- Bit 6 Reserved, must be kept at reset value.
- Bit 5 **HSIDIVF**: HSI divider flag  
Set and reset by hardware.  
As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF will go immediately to '0' when HSIDIV value is changed, and will be set back to '1' when the output frequency matches the value programmed into HSIDIV.  
0: new division ratio not yet propagated to **hsi(\_ker)\_ck** (default after reset)  
1: **hsi(\_ker)\_ck** clock frequency reflects the new HSIDIV value
- Bits 4:3 **HSIDIV[1:0]**: HSI clock divider  
Set and reset by software.  
These bits allow selecting a division ratio in order to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to '1'). In that case, the new HSIDIV value is ignored.  
00: Division by 1, **hsi(\_ker)\_ck** = 64 MHz (default after reset)  
01: Division by 2, **hsi(\_ker)\_ck** = 32 MHz  
10: Division by 4, **hsi(\_ker)\_ck** = 16 MHz  
11: Division by 8, **hsi(\_ker)\_ck** = 8 MHz

**Bit 2 HSIRDY:** HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)

1: HSI clock is ready

**Bit 1 HSIKERON:** High Speed Internal clock enable in Stop mode

Set and reset by software to force the HSI to ON, even in Stop mode, in order to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.

0: no effect on HSI (default after reset)

1: HSI is forced to ON even in Stop mode

**Bit 0 HSION:** High Speed Internal clock enable

Set and cleared by software.

Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = '0' or STOPKERWUCK = '0'.

Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a failure of the HSE which is used as the system clock source.

This bit cannot be cleared if the HSI is used directly (via SW mux) as system clock or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to '1').

0: HSI is OFF

1: HSI is ON (default after reset)

### 8.7.3 RCC Internal Clock Source Calibration Register (RCC\_ICSCR)

Address offset: 0x004

Reset value: 0x4xxx 0xxx

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CSITRIM[4:0]					CSICAL[7:0]					HSITRIM[5:4]				
	rw					r					rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSITRIM[3:0]					HSICAL[11:0]										
rw					r										

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **CSITRIM[4:0]**: CSI clock trimming

Set by software to adjust calibration.

CSITRIM field is added to the engineering Option Bytes loaded during reset phase (FLASH\_CSI\_opt) in order to form the calibration trimming value.

CSICAL = CSITRIM + FLASH\_CSI\_opt.

*Note: The reset value of the field is 0x10.*

Bits 25:18 **CSICAL[7:0]**: CSI clock calibration

Set by hardware by option byte loading during system reset **nreset**.

Adjusted by software through trimming bits CSITRIM.

This field represents the sum of engineering Option Byte calibration value and CSITRIM bits value

Bits 17:12 **HSITRIM[5:0]**: HSI clock trimming

Set by software to adjust calibration.

HSITRIM field is added to the engineering Option Bytes loaded during reset phase (FLASH\_HSI\_opt) in order to form the calibration trimming value.

HSICAL = HSITRIM + FLASH\_HSI\_opt.

*Note: The reset value of the field is 0x20.*

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

Set by hardware by option byte loading during system reset **nreset**.

Adjusted by software through trimming bits HSITRIM.

This field represents the sum of engineering Option Byte calibration value and HSITRIM bits value.

**8.7.4 RCC Clock Recovery RC Register (RCC\_CRRCR)**

Address offset: 0x008

Reset value: 0x0000 0xxx

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[9:0]									
						r									

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **HSI48CAL[9:0]**: Internal RC 48 MHz clock calibration

Set by hardware by option byte loading during system reset **nreset**.

Read-only.

### 8.7.5 RCC Clock Configuration Register (RCC\_CFGR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCO2[2:0]			MCO2PRE[3:0]				MCO1[2:0]			MCO11PRE[3:0]			Res.	Res.	
rw			rw				rw			rw					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMPRE	HRTIMSEL	RTCPRE[5:0]					STOPKERWUICK	STOPWUICK	SWS[2:0]			SW[2:0]			
		rw							rw	rw	r			rw	

Bits 31:29 **MCO2[2:0]**: Micro-controller clock output 2  
 Set and cleared by software. Clock source selection may generate glitches on MCO2. It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.  
 000: System clock selected (**sys\_ck**) (default after reset)  
 001: PLL2 oscillator clock selected (**pll2\_p\_ck**)  
 010: HSE clock selected (**hse\_ck**)  
 011: PLL1 clock selected (**pll1\_p\_ck**)  
 100: CSI clock selected (**csi\_ck**)  
 101: LSI clock selected (**lsi\_ck**)  
 others: reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler  
 Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.  
 0000: prescaler disabled (default after reset)  
 0001: division by 1 (bypass)  
 0010: division by 2  
 0011: division by 3  
 0100: division by 4  
 ...  
 1111: division by 15

Bits 24:22 **MCO1[2:0]**: Micro-controller clock output 1  
 Set and cleared by software. Clock source selection may generate glitches on MCO1. It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.  
 000: HSI clock selected (**hsi\_ck**) (default after reset)  
 001: LSE oscillator clock selected (**lse\_ck**)  
 010: HSE clock selected (**hse\_ck**)  
 011: PLL1 clock selected (**pll1\_q\_ck**)  
 100: HSI48 clock selected (**hsi48\_ck**)  
 others: reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: prescaler disabled (default after reset)

0001: division by 1 (bypass)

0010: division by 2

0011: division by 3

0100: division by 4

...

1111: division by 15

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **TIMPRE**: Timers clocks prescaler selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.

0: The Timers kernel clock is equal to **rcc\_hclk1** if D2PPREx is corresponding to division by 1 or 2, else it is equal to  $2 \times F_{\text{rcc\_pclkx\_d2}}$  (default after reset)

1: The Timers kernel clock is equal to **rcc\_hclk1** if D2PPREx is corresponding to division by 1, 2 or 4, else it is equal to  $4 \times F_{\text{rcc\_pclkx\_d2}}$

Please refer to [Table 48: Ratio between clock timer and pclk](#)

Bit 14 **HRTIMSEL**: High Resolution Timer clock prescaler selection

This bit is set and reset by software to control the clock frequency of high resolution the timer (HRTIM).

0: The HRTIM prescaler clock source is the same as other timers. (default after reset)

1: The HRTIM prescaler clock source is the CPU clock (**rcc\_c\_ck**).

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE to generate a clock for RTC.

Caution: The software has to set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

000000: no clock (default after reset)

000001: no clock

000010: HSE/2

000011: HSE/3

000100: HSE/4

...

111110: HSE/62

111111: HSE/63

Bit 7 **STOPKERWUCK**: Kernel clock selection after a wake up from system Stop

Set and reset by software to select the Kernel wakeup clock from system Stop.

0: The HSI is selected as wake up clock from system Stop (default after reset)

1: The CSI is selected as wake up clock from system Stop

See [Section 8.5.7: Handling clock generators in Stop and Standby mode](#) for details.

Bit 6 **STOPWUCK**: System clock selection after a wake up from system Stop

Set and reset by software to select the system wakeup clock from system Stop.

The selected clock is also used as emergency clock for the Clock Security System on HSE.

0: The HSI is selected as wake up clock from system Stop (default after reset)

1: The CSI is selected as wake up clock from system Stop

See [Section 8.5.7: Handling clock generators in Stop and Standby mode](#) for details.

**Caution:** STOPWUCK must not be modified when the Clock Security System is enabled (by HSECSSON bit) and the system clock is HSE (SWS="10") or a switch on HSE is requested (SW="10").

Bits 5:3 **SWS[2:0]**: System clock switch status

Set and reset by hardware to indicate which clock source is used as system clock.

000: HSI used as system clock (**hsi\_ck**) (default after reset)

001: CSI used as system clock (**csi\_ck**)

010: HSE used as system clock (**hse\_ck**)

011: PLL1 used as system clock (**pll1\_p\_ck**)

others: Reserved

Bits 2:0 **SW[2:0]**: System clock switch

Set and reset by software to select system clock source (**sys\_ck**).

Set by hardware in order to:

- force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode
- force the selection of the HSI in case of failure of the HSE when used directly or indirectly as system clock.

000: HSI selected as system clock (**hsi\_ck**) (default after reset)

001: CSI selected as system clock (**csi\_ck**)

010: HSE selected as system clock (**hse\_ck**)

011: PLL1 selected as system clock (**pll1\_p\_ck**)

others: Reserved

### 8.7.6 RCC Domain 1 Clock Configuration Register (RCC\_D1CFGR)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	D1CPRE[3:0]				Res.	D1PPRE[2:0]			HPRE[3:0]			
				rw					rw			rw			

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **D1CPRE[3:0]**: D1 domain Core prescaler

Set and reset by software to control D1 domain CPU clock division factor.

Changing this division ratio has an impact on the frequency of the CPU clock, and all bus matrix clocks.

The clocks are divided by the new prescaler factor. This factor ranges from 1 to 16 periods of the slowest APB clock among **rcc\_pclk[4:1]** after D1CPRE update. The application can check if the new division factor is taken into account by reading back this register.

0xxx: **sys\_ck** not divided (default after reset)

1000: **sys\_ck** divided by 2

1001: **sys\_ck** divided by 4

1010: **sys\_ck** divided by 8

1011: **sys\_ck** divided by 16

1100: **sys\_ck** divided by 64

1101: **sys\_ck** divided by 128

1110: **sys\_ck** divided by 256

1111: **sys\_ck** divided by 512

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **D1PPRE[2:0]**: D1 domain APB3 prescaler

Set and reset by software to control the division factor of **rcc\_pclk3**.

The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc\_hclk3** after D1PPRE write.

0xx: **rcc\_pclk3** = **rcc\_hclk3** (default after reset)

100: **rcc\_pclk3** = **rcc\_hclk3** / 2

101: **rcc\_pclk3** = **rcc\_hclk3** / 4

110: **rcc\_pclk3** = **rcc\_hclk3** / 8

111: **rcc\_pclk3** = **rcc\_hclk3** / 16

Bits 3:0 **HPRE[3:0]**: D1 domain AHB prescaler

Set and reset by software to control the division factor of **rcc\_hclk3** and **rcc\_ahbclk**. Changing this division ratio has an impact on the frequency of all bus matrix clocks.

0xxx: **rcc\_hclk3** = **sys\_d1cpre\_ck** (default after reset)

1000: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 2

1001: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 4

1010: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 8

1011: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 16

1100: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 64

1101: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 128

1110: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 256

1111: **rcc\_hclk3** = **sys\_d1cpre\_ck** / 512

*Note: The clocks are divided by the new prescaler factor from 1 to 16 periods of the slowest APB clock among **rcc\_pclk[4:1]** after HPRE update.*

*Note: Note also that **rcc\_hclk3** = **rcc\_ahbclk**.*

**Caution:** Care must be taken when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change and before lowering the  $V_{CORE}$  voltage, this register must be read in order to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application has to program a correct value in HPRE to make sure that the system frequency does not exceed the maximum frequency.

### 8.7.7 RCC Domain 2 Clock Configuration Register (RCC\_D2CFGR)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	D2PPRE2[2:0]			Res.	D2PPRE1[2:0]			Res.	Res.	Res.	Res.
					rw				rw						

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **D2PPRE2[2:0]**: D2 domain APB2 prescaler

Set and reset by software to control D2 domain APB2 clock division factor.

The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc\_hclk1** after D2PPRE2 write.

0xx: **rcc\_pclk2** = **rcc\_hclk1** (default after reset)

100: **rcc\_pclk2** = **rcc\_hclk1** / 2

101: **rcc\_pclk2** = **rcc\_hclk1** / 4

110: **rcc\_pclk2** = **rcc\_hclk1** / 8

111: **rcc\_pclk2** = **rcc\_hclk1** / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **D2PPRE1[2:0]**: D2 domain APB1 prescaler

Set and reset by software to control D2 domain APB1 clock division factor.

The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc\_hclk1** after D2PPRE1 write.

0xx: **rcc\_pclk1** = **rcc\_hclk1** (default after reset)

100: **rcc\_pclk1** = **rcc\_hclk1** / 2

101: **rcc\_pclk1** = **rcc\_hclk1** / 4

110: **rcc\_pclk1** = **rcc\_hclk1** / 8

111: **rcc\_pclk1** = **rcc\_hclk1** / 16

Bits 3:0 Reserved, must be kept at reset value.

### 8.7.8 RCC Domain 3 Clock Configuration Register (RCC\_D3CFGR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	D3PPRE[2:0]			Res.			
									rw						

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **D3PPRE[2:0]**: D3 domain APB4 prescaler

Set and reset by software to control D3 domain APB4 clock division factor.

The clock is divided by the new prescaler factor from 1 to 16 cycles of **rcc\_hclk4** after D3PPRE write.

0xx: **rcc\_pclk4** = **rcc\_hclk4** (default after reset)

100: **rcc\_pclk4** = **rcc\_hclk4** / 2

101: **rcc\_pclk4** = **rcc\_hclk4** / 4

110: **rcc\_pclk4** = **rcc\_hclk4** / 8

111: **rcc\_pclk4** = **rcc\_hclk4** / 16

Bits 3:0 Reserved, must be kept at reset value.

### 8.7.9 RCC PLLs Clock Source Selection Register (RCC\_PLLCKSELR)

Address offset: 0x028

Reset value: 0x0202 0200

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	DIVM3[5:0]					Res.	Res.	DIVM2[5:4]		
						rw							rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIVM2[3:0]				Res.	Res.	DIVM1[5:0]					Res.	Res.	PLLSRC[1:0]		
rw						rw							rw		

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **DIVM3[5:0]**: Prescaler for PLL3

Set and cleared by software to configure the prescaler of the PLL3.

The hardware does not allow any modification of this prescaler when PLL3 is enabled (PLL3ON = '1').

In order to save power when PLL3 is not used, the value of DIVM3 must be set to '0'.

000000: prescaler disabled (default after reset)

000001: division by 1 (bypass)

000010: division by 2

000011: division by 3

...

100000: division by 32 (default after reset)

...

111111: division by 63

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **DIVM2[5:0]**: Prescaler for PLL2

Set and cleared by software to configure the prescaler of the PLL2.

The hardware does not allow any modification of this prescaler when PLL2 is enabled (PLL2ON = '1').

In order to save power when PLL2 is not used, the value of DIVM2 must be set to '0'.

000000: prescaler disabled

000001: division by 1 (bypass)

000010: division by 2

000011: division by 3

...

100000: division by 32 (default after reset)

...

111111: division by 63

Bits 11:10 Reserved, must be kept at reset value.

**Bits 9:4 DIVM1[5:0]:** Prescaler for PLL1

Set and cleared by software to configure the prescaler of the PLL1.

The hardware does not allow any modification of this prescaler when PLL1 is enabled (PLL1ON = '1').

In order to save power when PLL1 is not used, the value of DIVM1 must be set to '0'.

000000: prescaler disabled

000001: division by 1 (bypass)

000010: division by 2

000011: division by 3

...

100000: division by 32 (default after reset)

...

111111: division by 63

Bits 3:2 Reserved, must be kept at reset value.

**Bits 1:0 PLLSRC[1:0]:** DIVMx and PLLs clock source selection

Set and reset by software to select the PLL clock source.

These bits can be written only when all PLLs are disabled.

In order to save power, when no PLL is used, the value of PLLSRC must be set to '11'.

00: HSI selected as PLL clock (**hsi\_ck**) (default after reset)

01: CSI selected as PLL clock (**csi\_ck**)

10: HSE selected as PLL clock (**hse\_ck**)

11: No clock send to DIVMx divider and PLLs

### 8.7.10 RCC PLLs Configuration Register (RCC\_PLLCFGR)

Address offset: 0x02C

Reset value: 0x01FF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw		rw	rw	rw		rw	rw	rw		rw	rw

Bits 31:25 Reserved, must be kept at reset value.

- Bit 24 DIVR3EN:** PLL3 DIVR divider output enable  
 Set and reset by software to enable the **pll3\_r\_ck** output of the PLL3.  
 To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.  
 This bit can be written only when the PLL3 is disabled (PLL3ON = '0' and PLL3RDY = '0').  
 0: **pll3\_r\_ck** output is disabled  
 1: **pll3\_r\_ck** output is enabled (default after reset)
- Bit 23 DIVQ3EN:** PLL3 DIVQ divider output enable  
 Set and reset by software to enable the **pll3\_q\_ck** output of the PLL3.  
 To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.  
 This bit can be written only when the PLL3 is disabled (PLL3ON = '0' and PLL3RDY = '0').  
 0: **pll3\_q\_ck** output is disabled  
 1: **pll3\_q\_ck** output is enabled (default after reset)
- Bit 22 DIVP3EN:** PLL3 DIVP divider output enable  
 Set and reset by software to enable the **pll3\_p\_ck** output of the PLL3.  
 This bit can be written only when the PLL3 is disabled (PLL3ON = '0' and PLL3RDY = '0').  
 To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.  
 0: **pll3\_p\_ck** output is disabled  
 1: **pll3\_p\_ck** output is enabled (default after reset)
- Bit 21 DIVR2EN:** PLL2 DIVR divider output enable  
 Set and reset by software to enable the **pll2\_r\_ck** output of the PLL2.  
 To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.  
 This bit can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').  
 0: **pll2\_r\_ck** output is disabled  
 1: **pll2\_r\_ck** output is enabled (default after reset)
- Bit 20 DIVQ2EN:** PLL2 DIVQ divider output enable  
 Set and reset by software to enable the **pll2\_q\_ck** output of the PLL2.  
 To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.  
 This bit can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').  
 0: **pll2\_q\_ck** output is disabled  
 1: **pll2\_q\_ck** output is enabled (default after reset)

**Bit 19 DIVP2EN:** PLL2 DIVP divider output enable

Set and reset by software to enable the **pll2\_p\_ck** output of the PLL2.

This bit can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').

To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.

0: **pll2\_p\_ck** output is disabled

1: **pll2\_p\_ck** output is enabled (default after reset)

**Bit 18 DIVR1EN:** PLL1 DIVR divider output enable

Set and reset by software to enable the **pll1\_r\_ck** output of the PLL1.

To save power, DIVR3EN and DIVR3 bits must be set to '0' when the **pll3\_r\_ck** is not used.

This bit can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').

0: **pll1\_r\_ck** output is disabled

1: **pll1\_r\_ck** output is enabled (default after reset)

**Bit 17 DIVQ1EN:** PLL1 DIVQ divider output enable

Set and reset by software to enable the **pll1\_q\_ck** output of the PLL1.

In order to save power, when the **pll1\_q\_ck** output of the PLL1 is not used, the **pll1\_q\_ck** must be disabled.

This bit can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').

0: **pll1\_q\_ck** output is disabled

1: **pll1\_q\_ck** output is enabled (default after reset)

**Bit 16 DIVP1EN:** PLL1 DIVP divider output enable

Set and reset by software to enable the **pll1\_p\_ck** output of the PLL1.

This bit can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').

In order to save power, when the **pll1\_p\_ck** output of the PLL1 is not used, the **pll1\_p\_ck** must be disabled.

0: **pll1\_p\_ck** output is disabled

1: **pll1\_p\_ck** output is enabled (default after reset)

Bits 15:12 Reserved, must be kept at reset value.

**Bits 11:10 PLL3RGE[1:0]:** PLL3 input frequency range

Set and reset by software to select the proper reference frequency range used for PLL3.

These bits must be written before enabling the PLL3.

00: The PLL3 input (**ref3\_ck**) clock range frequency is between 1 and 2 MHz (default after reset)

01: The PLL3 input (**ref3\_ck**) clock range frequency is between 2 and 4 MHz

10: The PLL3 input (**ref3\_ck**) clock range frequency is between 4 and 8 MHz

11: The PLL3 input (**ref3\_ck**) clock range frequency is between 8 and 16 MHz

**Bit 9 PLL3VCOSEL:** PLL3 VCO selection

Set and reset by software to select the proper VCO frequency range used for PLL3.

This bit must be written before enabling the PLL3.

0: Wide VCO range:192 to 836 MHz (default after reset)

1: Medium VCO range:150 to 420 MHz

**Bit 8 PLL3FRACEN:** PLL3 fractional latch enable

Set and reset by software to latch the content of FRACN3 into the Sigma-Delta modulator.

In order to latch the FRACN3 value into the Sigma-Delta modulator, PLL3FRACEN must be set to '0', then set to '1': the transition 0 to 1 transfers the content of FRACN3 into the modulator. Please refer to [Section : PLL initialization phase](#) for additional information.

**Bits 7:6 PLL2RGE[1:0]:** PLL2 input frequency range

Set and reset by software to select the proper reference frequency range used for PLL2.

These bits must be written before enabling the PLL2.

00: The PLL2 input (**ref2\_ck**) clock range frequency is between 1 and 2 MHz (default after reset)

01: The PLL2 input (**ref2\_ck**) clock range frequency is between 2 and 4 MHz

10: The PLL2 input (**ref2\_ck**) clock range frequency is between 4 and 8 MHz

11: The PLL2 input (**ref2\_ck**) clock range frequency is between 8 and 16 MHz

**Bit 5 PLL2VCOSEL:** PLL2 VCO selection

Set and reset by software to select the proper VCO frequency range used for PLL2.

This bit must be written before enabling the PLL2.

0: Wide VCO range: 192 to 836 MHz (default after reset)

1: Medium VCO range: 150 to 420 MHz

**Bit 4 PLL2FRACEN:** PLL2 fractional latch enable

Set and reset by software to latch the content of FRACN2 into the Sigma-Delta modulator.

In order to latch the FRACN2 value into the Sigma-Delta modulator, PLL2FRACEN must be set to '0', then set to '1': the transition 0 to 1 transfers the content of FRACN2 into the modulator. Please refer to [Section : PLL initialization phase](#) for additional information.

**Bits 3:2 PLL1RGE[1:0]:** PLL1 input frequency range

Set and reset by software to select the proper reference frequency range used for PLL1.

This bit must be written before enabling the PLL1.

00: The PLL1 input (**ref1\_ck**) clock range frequency is between 1 and 2 MHz (default after reset)

01: The PLL1 input (**ref1\_ck**) clock range frequency is between 2 and 4 MHz

10: The PLL1 input (**ref1\_ck**) clock range frequency is between 4 and 8 MHz

11: The PLL1 input (**ref1\_ck**) clock range frequency is between 8 and 16 MHz

**Bit 1 PLL1VCOSEL:** PLL1 VCO selection

Set and reset by software to select the proper VCO frequency range used for PLL1.

These bits must be written before enabling the PLL1.

0: Wide VCO range: 192 to 836 MHz (default after reset)

1: Medium VCO range: 150 to 420 MHz

**Bit 0 PLL1FRACEN:** PLL1 fractional latch enable

Set and reset by software to latch the content of FRACN1 into the Sigma-Delta modulator.

In order to latch the FRACN1 value into the Sigma-Delta modulator, PLL1FRACEN must be set to '0', then set to '1': the transition 0 to 1 transfers the content of FRACN1 into the modulator. Please refer to [Section : PLL initialization phase](#) for additional information.

### 8.7.11 RCC PLL1 Dividers Configuration Register (RCC\_PLL1DIVR)

Address offset: 0x030

Reset value: 0x0101 0280

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.		DIVR1[6:0]						Res.		DIVQ1[6:0]					
		rw								rw

DIVP1[6:0]								DIVN1[8:0]							
rw								rw							

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR1[6:0]**: PLL1 DIVR division factor

Set and reset by software to control the frequency of the **pll1\_r\_ck** clock.

These bits can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').

0000000: **pll1\_r\_ck** = **vco1\_ck**

0000001: **pll1\_r\_ck** = **vco1\_ck** / 2 (default after reset)

0000010: **pll1\_r\_ck** = **vco1\_ck** / 3

0000011: **pll1\_r\_ck** = **vco1\_ck** / 4

...

1111111: **pll1\_r\_ck** = **vco1\_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ1[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the **pll1\_q\_ck** clock.

These bits can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').

0000000: **pll1\_q\_ck** = **vco1\_ck**

0000001: **pll1\_q\_ck** = **vco1\_ck** / 2 (default after reset)

0000010: **pll1\_q\_ck** = **vco1\_ck** / 3

0000011: **pll1\_q\_ck** = **vco1\_ck** / 4

...

1111111: **pll1\_q\_ck** = **vco1\_ck** / 128

Bits 15:9 **DIVP1[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the **pll1\_p\_ck** clock.

These bits can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').

Note that odd division factors are not allowed.

0000000: Not allowed

0000001: **pll1\_p\_ck** = **vco1\_ck** / 2 (default after reset)

0000010: Not allowed

0000011: **pll1\_p\_ck** = **vco1\_ck** / 4

...

1111111: **pll1\_p\_ck** = **vco1\_ck** / 128

Bits 8:0 **DIVN1[8:0]**: Multiplication factor for PLL1 VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits can be written only when the PLL is disabled (PLL1ON = '0' and PLL1RDY = '0').

0x003: DIVN1 = 4

0x004: DIVN1 = 5

0x005: DIVN1 = 6

...

0x080: DIVN1 = 129 (default after reset)

...

0x1FF: DIVN1 = 512

Others: wrong configurations

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL1VCOSEL = '0'
- 150 to 420 MHz if PLL1VCOSEL = '1'
- 

VCO output frequency =  $F_{\text{ref1\_ck}} \times \text{DIVN1}$ , when fractional value 0 has been loaded into **FRACN1**, with:

- DIVN1 between 4 and 512
- The input frequency  $F_{\text{ref1\_ck}}$  between 1MHz and 16 MHz

### 8.7.12 RCC PLL1 Fractional Divider Register (RCC\_PLL1FRACR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRACN1[12:0]												Res.	Res.	Res.	
rw															

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN1[12:0]**: Fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL1VCOSEL = '0'
- 150 to 420 MHz if PLL1VCOSEL = '1'

VCO output frequency =  $F_{ref1\_ck} \times (DIVN1 + (FRACN1 / 2^{13}))$ , with

- DIVN1 shall be between 4 and 512
- FRACN1 can be between 0 and  $2^{13} - 1$
- The input frequency  $F_{ref1\_ck}$  shall be between 1 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit PLL1FRACEN to '0',
- write the new fractional value into FRACN1,
- set the bit PLL1FRACEN to '1'.

Bits 2:0 Reserved, must be kept at reset value.

### 8.7.13 RCC PLL2 Dividers Configuration Register (RCC\_PLL2DIVR)

Address offset: 0x038

Reset value: 0x0101 0280

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DIVP2[6:0]								DIVN2[8:0]							
rw								rw							

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR2[6:0]**: PLL2 DIVR division factor

Set and reset by software to control the frequency of the **pll2\_r\_ck** clock.

These bits can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').

0000000: **pll2\_r\_ck** = **vco2\_ck**

0000001: **pll2\_r\_ck** = **vco2\_ck** / 2 (default after reset)

0000010: **pll2\_r\_ck** = **vco2\_ck** / 3

0000011: **pll2\_r\_ck** = **vco2\_ck** / 4

...

1111111: **pll2\_r\_ck** = **vco2\_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ2[6:0]**: PLL2 DIVQ division factor

Set and reset by software to control the frequency of the **pll2\_q\_ck** clock.

These bits can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').

0000000: **pll2\_q\_ck** = **vco2\_ck**

0000001: **pll2\_q\_ck** = **vco2\_ck** / 2 (default after reset)

0000010: **pll2\_q\_ck** = **vco2\_ck** / 3

0000011: **pll2\_q\_ck** = **vco2\_ck** / 4

...

1111111: **pll2\_q\_ck** = **vco2\_ck** / 128

Bits 15:9 **DIVP2[6:0]**: PLL2 DIVP division factor

Set and reset by software to control the frequency of the **pll2\_p\_ck** clock.

These bits can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').

0000000: **pll2\_p\_ck** = **vco2\_ck**

0000001: **pll2\_p\_ck** = **vco2\_ck** / 2 (default after reset)

0000010: **pll2\_p\_ck** = **vco2\_ck** / 3

0000011: **pll2\_p\_ck** = **vco2\_ck** / 4

...

1111111: **pll2\_p\_ck** = **vco2\_ck** / 128

Bits 8:0 **DIVN2[8:0]**: Multiplication factor for PLL2 VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits can be written only when the PLL is disabled (PLL2ON = '0' and PLL2RDY = '0').

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL2VCOSEL = '0'
- 150 to 420 MHz if PLL2VCOSEL = '1'

VCO output frequency =  $F_{ref2\_ck} \times DIVN2$ , when fractional value 0 has been loaded into FRACN2, with

- DIVN2 between 4 and 512
- The input frequency  $F_{ref2\_ck}$  between 1MHz and 16MHz

0x003: DIVN2 = 4

0x004: DIVN2 = 5

0x005: DIVN2 = 6

...

0x080: DIVN2 = 129 (default after reset)

...

0x1FF: DIVN2 = 512

Others: wrong configurations

### 8.7.14 RCC PLL2 Fractional Divider Register (RCC\_PLL2FRACR)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRACN2[12:0]												Res.	Res.	Res.	
rw															

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN2[12:0]**: Fractional part of the multiplication factor for PLL2 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL2VCOSEL = '0'
- 150 to 420 MHz if PLL2VCOSEL = '1'

VCO output frequency =  $F_{ref2\_ck} \times (DIVN2 + (FRACN2 / 2^{13}))$ , with

- DIVN2 shall be between 4 and 512
- FRACN2 can be between 0 and  $2^{13} - 1$
- The input frequency  $F_{ref2\_ck}$  shall be between 1 and 16 MHz

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit PLL2FRACEN to '0',
- write the new fractional value into FRACN2,
- set the bit PLL2FRACEN to '1'.

Bits 2:0 Reserved, must be kept at reset value.

### 8.7.15 RCC PLL3 Dividers Configuration Register (RCC\_PLL3DIVR)

Address offset: 0x040

Reset value: 0x0101 0280

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DIVP3[6:0]								DIVN3[8:0]							
rw								rw							

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR3[6:0]**: PLL3 DIVR division factor

Set and reset by software to control the frequency of the **pll3\_r\_ck** clock.

These bits can be written only when the PLL3 is disabled (PLL3ON = '0' and PLL3RDY = '0').

0000000: **pll3\_r\_ck** = **vco3\_ck**

0000001: **pll3\_r\_ck** = **vco3\_ck** / 2 (default after reset)

0000010: **pll3\_r\_ck** = **vco3\_ck** / 3

0000011: **pll3\_r\_ck** = **vco3\_ck** / 4

...

1111111: **pll3\_r\_ck** = **vco3\_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ3[6:0]**: PLL3 DIVQ division factor

Set and reset by software to control the frequency of the **pll3\_q\_ck** clock.

These bits can be written only when the PLL3 is disabled (PLL3ON = '0' and PLL3RDY = '0').

0000000: **pll3\_q\_ck** = **vco3\_ck**

0000001: **pll3\_q\_ck** = **vco3\_ck** / 2 (default after reset)

0000010: **pll3\_q\_ck** = **vco3\_ck** / 3

0000011: **pll3\_q\_ck** = **vco3\_ck** / 4

...

1111111: **pll3\_q\_ck** = **vco3\_ck** / 128

Bits 15:9 **DIVP3[6:0]**: PLL3 DIVP division factor

Set and reset by software to control the frequency of the **pll3\_p\_ck** clock.

These bits can be written only when the PLL3 is disabled (PLL3ON = '0' and PLL3RDY = '0').

0000000: **pll3\_p\_ck** = **vco3\_ck**

0000001: **pll3\_p\_ck** = **vco3\_ck** / 2 (default after reset)

0000010: **pll3\_p\_ck** = **vco3\_ck** / 3

0000011: **pll3\_p\_ck** = **vco3\_ck** / 4

...

1111111: **pll3\_p\_ck** = **vco3\_ck** / 128

Bits 8:0 **DIVN3[7:0]**: Multiplication factor for PLL3 VCO

Set and reset by software to control the multiplication factor of the VCO.

These bits can be written only when the PLL is disabled (PLL3ON = '0' and PLL3RDY = '0').

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL3VCOSEL = '0'
- 150 to 420 MHz if PLL3VCOSEL = '1'

VCO output frequency =  $F_{ref3\_ck} \times DIVN3$ , when fractional value 0 has been loaded into FRACN3, with

- DIVN3 between 4 and 512
- The input frequency  $F_{ref3\_ck}$  between 1MHz and 16MHz

0x003: DIVN3 = 4

0x004: DIVN3 = 5

0x005: DIVN3 = 6

...

0x080: DIVN3 = 129 (default after reset)

...

0x1FF: DIVN3 = 512

Others: wrong configurations

### 8.7.16 RCC PLL3 Fractional Divider Register (RCC\_PLL3FRACR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

FRACN3[12:0]												Res.	Res.	Res.	
rw															

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN3[12:0]**: Fractional part of the multiplication factor for PLL3 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL3 VCO.

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL3VCOSEL = '0'
- 150 to 420 MHz if PLL3VCOSEL = '1'

VCO output frequency =  $F_{ref3\_ck} \times (DIVN3 + (FRACN3 / 2^{13}))$ , with

- DIVN3 shall be between 4 and 512
- FRACN3 can be between 0 and  $2^{13} - 1$
- The input frequency  $F_{ref3\_ck}$  shall be between 1 and 16 MHz

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit PLL1FRACEN to '0',
- write the new fractional value into FRACN1,
- set the bit PLL1FRACEN to '1'.

Bits 2:0 Reserved, must be kept at reset value.

### 8.7.17 RCC Domain 1 Kernel Clock Configuration Register (RCC\_D1CCIPR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

However the user has to make sure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Please refer to [Section : Clock switches and gating](#).

Bit 31 **SWPSEL**: SWPMI kernel clock source selection  
 Set and reset by software.  
 0: **pclk** is selected as SWPMI kernel clock (default after reset)  
 1: **hsi\_ker\_ck** clock is selected as SWPMI kernel clock

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **FDCANSEL**: FDCAN kernel clock source selection  
 Set and reset by software.  
 00: **hse\_ck** clock is selected as FDCAN kernel clock (default after reset)  
 01: **pll1\_q\_ck** clock is selected as FDCAN kernel clock  
 10: **pll2\_q\_ck** clock is selected as FDCAN kernel clock  
 11: reserved, the kernel clock is disabled

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **DFSDM1SEL**: DFSDM1 kernel **Clk** clock source selection  
 Set and reset by software.  
*Note: the DFSDM1 Aclk Clock Source Selection is done by SAI1SEL.*  
 0: **rcc\_pclk2** is selected as DFSDM1 Clk kernel clock (default after reset)  
 1: **sys\_ck** clock is selected as DFSDM1 Clk kernel clock

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **SPDIFSEL[1:0]**: SPDIFRX kernel clock source selection  
 00: **pll1\_q\_ck** clock selected as SPDIFRX kernel clock (default after reset)  
 01: **pll2\_r\_ck** clock selected as SPDIFRX kernel clock  
 10: **pll3\_r\_ck** clock selected as SPDIFRX kernel clock  
 11: **hsi\_ker\_ck** clock selected as SPDIFRX kernel clock

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **SPI45SEL[2:0]**: SPI4 and 5 kernel clock source selection

Set and reset by software.

000: APB clock is selected as kernel clock (default after reset)

001: **pll2\_q\_ck** clock is selected as kernel clock

010: **pll3\_q\_ck** clock is selected as kernel clock

011: **hsi\_ker\_ck** clock is selected as kernel clock

100: **csi\_ker\_ck** clock is selected as kernel clock

101: **hse\_ck** clock is selected as kernel clock

others: reserved, the kernel clock is disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **SPI123SEL[2:0]**: SPI/I2S1,2 and 3 kernel clock source selection

Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to [Section : Clock switches and gating](#) for additional information.

000: **pll1\_q\_ck** clock selected as SPI/I2S1,2&3 kernel clock (default after reset)

001: **pll2\_p\_ck** clock selected as SPI/I2S1,2&3 kernel clock

010: **pll3\_p\_ck** clock selected as SPI/I2S1,2&3 kernel clock

011: I2S\_CKIN clock selected as SPI/I2S1,2&3 kernel clock

100: **per\_ck** clock selected as SPI/I2S1,2&3 kernel clock

others: reserved, the kernel clock is disabled

*Note: I2S\_CKIN is an external clock taken from a pin.*

Bits 11:9 Reserved, must be kept at reset value.

Bits 8:6 **SAI23SEL[2:0]**: SAI2 and SAI3 kernel clock source selection  
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to [Section : Clock switches and gating](#) for additional information.

000: **pll1\_q\_ck** clock selected as SAI2 & SAI3 kernel clock (default after reset)

001: **pll2\_p\_ck** clock selected as SAI2 & SAI3 kernel clock

010: **pll3\_p\_ck** clock selected as SAI2 & SAI3 kernel clock

011: **I2S\_CKIN** clock selected as SAI2 & SAI3 kernel clock

100: **per\_ck** clock selected as SAI2 & SAI3 kernel clock

others: reserved, the kernel clock is disabled

*Note: I2S\_CKIN is an external clock taken from a pin.*

Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 **SAI1SEL[2:0]**: SAI1 and DFSDM1 kernel **Aclk** clock source selection  
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to [Section : Clock switches and gating](#) for additional information.

*Note: DFSDM1 Clock Source Selection is done by DFSDM1SEL.*

000: **pll1\_q\_ck** clock selected as SAI1 and DFSDM1 **Aclk** kernel clock (default after reset)

001: **pll2\_p\_ck** clock selected as SAI1 and DFSDM1 **Aclk** kernel clock

010: **pll3\_p\_ck** clock selected as SAI1 and DFSDM1 **Aclk** kernel clock

011: **I2S\_CKIN** clock selected as SAI1 and DFSDM1 **Aclk** kernel clock

100: **per\_ck** clock selected as SAI1 and DFSDM1 **Aclk** kernel clock

others: reserved, the kernel clock is disabled

*Note: I2S\_CKIN is an external clock taken from a pin.*

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SAI4BSEL[2:0]**: Sub-Block B of SAI4 kernel clock source selection

Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to [Section : Clock switches and gating](#) for additional information.

000: **pll1\_q\_ck** clock selected as kernel peripheral clock (default after reset)

001: **pll2\_p\_ck** clock selected as kernel peripheral clock

010: **pll3\_p\_ck** clock selected as kernel peripheral clock

011: **I2S\_CKIN** clock selected as kernel peripheral clock

100: **per\_ck** clock selected as kernel peripheral clock

others: reserved, the kernel clock is disabled

*Note: I2S\_CKIN is an external clock taken from a pin.*

Bits 23:21 **SAI4ASEL[2:0]**: Sub-Block A of SAI4 kernel clock source selection

Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to [Section : Clock switches and gating](#) for additional information.

000: **pll1\_q\_ck** clock selected as kernel peripheral clock (default after reset)

001: **pll2\_p\_ck** clock selected as kernel peripheral clock

010: **pll3\_p\_ck** clock selected as kernel peripheral clock

011: **I2S\_CKIN** clock selected as kernel peripheral clock

100: **per\_ck** clock selected as kernel peripheral clock

others: reserved, the kernel clock is disabled

*Note: I2S\_CKIN is an external clock taken from a pin.*

Bits 20:18 Reserved, must be kept at reset value.

Bits 17:16 **ADCSEL[1:0]**: SAR ADC kernel clock source selection

Set and reset by software.

00: **pll2\_p\_ck** clock selected as kernel peripheral clock (default after reset)

01: **pll3\_r\_ck** clock selected as kernel peripheral clock

10: **per\_ck** clock selected as kernel peripheral clock

others: reserved, the kernel clock is disabled

Bits 15:13 **LPTIM345SEL[2:0]**: LPTIM3,4,5 kernel clock source selection

Set and reset by software.

000: **rcc\_pclk4** clock selected as kernel peripheral clock (default after reset)

001: **pll2\_p\_ck** clock selected as kernel peripheral clock

010: **pll3\_r\_ck** clock selected as kernel peripheral clock

011: **lse\_ck** clock selected as kernel peripheral clock

100: **lsi\_ck** clock selected as kernel peripheral clock

101: **per\_ck** clock selected as kernel peripheral clock

others: reserved, the kernel clock is disabled

Bits 12:10 **LPTIM2SEL[2:0]**: LPTIM2 kernel clock source selection

Set and reset by software.

000: **rcc\_pclk4** clock selected as kernel peripheral clock (default after reset)

001: **pll2\_p\_ck** clock selected as kernel peripheral clock

010: **pll3\_r\_ck** clock selected as kernel peripheral clock

011: **lse\_ck** clock selected as kernel peripheral clock

100: **lsi\_ck** clock selected as kernel peripheral clock

101: **per\_ck** clock selected as kernel peripheral clock

others: reserved, the kernel clock is disabled

- Bits 9:8 **I2C4SEL[1:0]**: I2C4 kernel clock source selection  
Set and reset by software.  
00: **rcc\_pclk4** clock selected as kernel peripheral clock (default after reset)  
01: **pll3\_r\_ck** clock selected as kernel peripheral clock  
10: **hsi\_ker\_ck** clock selected as kernel peripheral clock  
11: **csi\_ker\_ck** clock selected as kernel peripheral clock
- Bits 7:3 Reserved, must be kept at reset value.
- Bits 2:0 **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection  
Set and reset by software.  
000: **rcc\_pclk\_d3** clock is selected as kernel peripheral clock (default after reset)  
001: **pll2\_q\_ck** clock is selected as kernel peripheral clock  
010: **pll3\_q\_ck** clock is selected as kernel peripheral clock  
011: **hsi\_ker\_ck** clock is selected as kernel peripheral clock  
100: **csi\_ker\_ck** clock is selected as kernel peripheral clock  
101: **lse\_ck** clock is selected as kernel peripheral clock  
others: reserved, the kernel clock is disabled

### 8.7.21 RCC Clock Source Interrupt Enable Register (RCC\_CIER)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	LSECSSIE	PLL3RDYIE	PLL2RDYIE	PLL1RDYIE	HSI48RDYIE	CSIRDYIE	HSERDYIE	HSIRDYIE	LSERDYIE	LSIRDYIE
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

**Bit 9 LSECSSIE:** LSE clock security system Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the Clock Security System on external 32 kHz oscillator.

0: LSE CSS interrupt disabled (default after reset)

1: LSE CSS interrupt enabled

**Bit 8 PLL3RDYIE:** PLL3 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL3 lock.

0: PLL3 lock interrupt disabled (default after reset)

1: PLL3 lock interrupt enabled

**Bit 7 PLL2RDYIE:** PLL2 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL2 lock.

0: PLL2 lock interrupt disabled (default after reset)

1: PLL2 lock interrupt enabled

**Bit 6 PLL1RDYIE:** PLL1 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL1 lock.

0: PLL1 lock interrupt disabled (default after reset)

1: PLL1 lock interrupt enabled

**Bit 5 HSI48RDYIE:** HSI48 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.

0: HSI48 ready interrupt disabled (default after reset)

1: HSI48 ready interrupt enabled

**Bit 4 CSIRDYIE:** CSI ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.

0: CSI ready interrupt disabled (default after reset)

1: CSI ready interrupt enabled

**Bit 3 HSERDYIE:** HSE ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.

0: HSE ready interrupt disabled (default after reset)

1: HSE ready interrupt enabled

**Bit 2 HSIRDYIE:** HSI ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.

0: HSI ready interrupt disabled (default after reset)

1: HSI ready interrupt enabled

**Bit 1 LSERDYIE:** LSE ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.

0: LSE ready interrupt disabled (default after reset)

1: LSE ready interrupt enabled

**Bit 0 LSIRDYIE:** LSI ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.

0: LSI ready interrupt disabled (default after reset)

1: LSI ready interrupt enabled

### 8.7.22 RCC Clock Source Interrupt Flag Register (RCC\_CIFR)

Address offset: 0x64

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSF	LSECSSF	PLL3RDYF	PLL2RDYF	PLL1RDYF	HSI48RDYF	CSIRDYF	HSERDYF	HSIRDYF	LSERDYF	LSIRDYF
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

**Bit 10 HSECSSF:** HSE clock security system Interrupt Flag

Reset by software by writing HSECSSC bit.

Set by hardware in case of HSE clock failure.

0: No clock security interrupt caused by HSE clock failure (default after reset)

1: Clock security interrupt caused by HSE clock failure

**Bit 9 LSECSSF:** LSE clock security system Interrupt Flag

Reset by software by writing LSECSSC bit.

Set by hardware when a failure is detected on the external 32 kHz oscillator and LSECSSIE is set.

0: No failure detected on the external 32 kHz oscillator (default after reset)

1: A failure is detected on the external 32 kHz oscillator

**Bit 8 PLL3RDYF:** PLL3 ready Interrupt Flag

Reset by software by writing PLL3RDYC bit.

Set by hardware when the PLL3 locks and PLL3RDYIE is set.

0: No clock ready interrupt caused by PLL3 lock (default after reset)

1: Clock ready interrupt caused by PLL3 lock

**Bit 7 PLL2RDYF:** PLL2 ready Interrupt Flag

Reset by software by writing PLL2RDYC bit.

Set by hardware when the PLL2 locks and PLL2RDYIE is set.

0: No clock ready interrupt caused by PLL2 lock (default after reset)

1: Clock ready interrupt caused by PLL2 lock

**Bit 6 PLL1RDYF:** PLL1 ready Interrupt Flag

Reset by software by writing PLL1RDYC bit.

Set by hardware when the PLL1 locks and PLL1RDYIE is set.

0: No clock ready interrupt caused by PLL1 lock (default after reset)

1: Clock ready interrupt caused by PLL1 lock

**Bit 5 HSI48RDYF:** HSI48 ready Interrupt Flag

Reset by software by writing HSI48RDYC bit.

Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.

0: No clock ready interrupt caused by the HSI48 oscillator (default after reset)

1: Clock ready interrupt caused by the HSI48 oscillator

- Bit 4 **CSIRDYF**: CSI ready Interrupt Flag  
Reset by software by writing CSIRDYC bit.  
Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.  
0: No clock ready interrupt caused by the CSI (default after reset)  
1: Clock ready interrupt caused by the CSI
- Bit 3 **HSERDYF**: HSE ready Interrupt Flag  
Reset by software by writing HSERDYC bit.  
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.  
0: No clock ready interrupt caused by the HSE (default after reset)  
1: Clock ready interrupt caused by the HSE
- Bit 2 **HSIRDYF**: HSI ready Interrupt Flag  
Reset by software by writing HSIRDYC bit.  
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.  
0: No clock ready interrupt caused by the HSI (default after reset)  
1: Clock ready interrupt caused by the HSI
- Bit 1 **LSERDYF**: LSE ready Interrupt Flag  
Reset by software by writing LSERDYC bit.  
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.  
0: No clock ready interrupt caused by the LSE (default after reset)  
1: Clock ready interrupt caused by the LSE
- Bit 0 **LSIRDYF**: LSI ready Interrupt Flag  
Reset by software by writing LSIRDYC bit.  
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.  
0: No clock ready interrupt caused by the LSI (default after reset)  
1: Clock ready interrupt caused by the LSI

### 8.7.23 RCC Clock Source Interrupt Clear Register (RCC\_CICR)

Address offset: 0x68

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSC	LSECSSC	PLL3RDYC	PLL2RDYC	PLL1RDYC	HSI48RDYC	CSIRDYC	HSERDYC	HSIRDYC	LSERDYC	LSIRDYC
					rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSC**: HSE clock security system Interrupt Clear

Set by software to clear HSECSSF.  
 Reset by hardware when clear done.  
 0: HSECSSF no effect (default after reset)  
 1: HSECSSF cleared

Bit 9 **LSECSSC**: LSE clock security system Interrupt Clear

Set by software to clear LSECSSF.  
 Reset by hardware when clear done.  
 0: LSECSSF no effect (default after reset)  
 1: LSECSSF cleared

Bit 8 **PLL3RDYC**: PLL3 ready Interrupt Clear

Set by software to clear PLL3RDYF.  
 Reset by hardware when clear done.  
 0: PLL3RDYF no effect (default after reset)  
 1: PLL3RDYF cleared

Bit 7 **PLL2RDYC**: PLL2 ready Interrupt Clear

Set by software to clear PLL2RDYF.  
 Reset by hardware when clear done.  
 0: PLL2RDYF no effect (default after reset)  
 1: PLL2RDYF cleared

Bit 6 **PLL1RDYC**: PLL1 ready Interrupt Clear

Set by software to clear PLL1RDYF.  
 Reset by hardware when clear done.  
 0: PLL1RDYF no effect (default after reset)  
 1: PLL1RDYF cleared

Bit 5 **HSI48RDYC**: HSI48 ready Interrupt Clear

Set by software to clear HSI48RDYF.  
 Reset by hardware when clear done.  
 0: HSI48RDYF no effect (default after reset)  
 1: HSI48RDYF cleared

- Bit 4 **CSIRDYC**: CSI ready Interrupt Clear  
Set by software to clear CSIRDYF.  
Reset by hardware when clear done.  
0: CSIRDYF no effect (default after reset)  
1: CSIRDYF cleared
- Bit 3 **HSERDYC**: HSE ready Interrupt Clear  
Set by software to clear HSERDYF.  
Reset by hardware when clear done.  
0: HSERDYF no effect (default after reset)  
1: HSERDYF cleared
- Bit 2 **HSIRDYC**: HSI ready Interrupt Clear  
Set by software to clear HSIRDYF.  
Reset by hardware when clear done.  
0: HSIRDYF no effect (default after reset)  
1: HSIRDYF cleared
- Bit 1 **LSERDYC**: LSE ready Interrupt Clear  
Set by software to clear LSERDYF.  
Reset by hardware when clear done.  
0: LSERDYF no effect (default after reset)  
1: LSERDYF cleared
- Bit 0 **LSIRDYC**: LSI ready Interrupt Clear  
Set by software to clear LSIRDYF.  
Reset by hardware when clear done.  
0: LSIRDYF no effect (default after reset)  
1: LSIRDYF cleared

### 8.7.24 RCC Backup Domain Control Register (RCC\_BDCR)

Address offset: 0x070

Reset value: 0x0000 0000, reset by Backup domain reset.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

After a system reset, the RCC\_BDCR register is write-protected. To modify this register, the DBP bit in the *PWR control register 1 (PWR\_CR1)* has to be set to '1'. RCC\_BDCR bits are only reset after a backup domain reset (see *Section 8.4.6: Backup domain reset*). Any other internal or external reset will not have any effect on these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BDRST
															r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	Res.	Res.	Res.	RTCSEL[1:0]		Res.	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
r/w						r/w			r	rs	r/w		r/w	r	r/w

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset

Set and reset by software.

0: Reset not activated (default after backup domain reset)

1: Resets the entire VSW domain

Bit 15 **RTCEN**: RTC clock enable

Set and reset by software.

0: **rtc\_ck** clock is disabled (default after backup domain reset)

1: **rtc\_ck** clock enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: RTC clock source selection

Set by software to select the clock source for the RTC. These bits can be written only one time (except in case of failure detection on LSE). These bits must be written before LSECSSON is enabled. The BDRST bit can be used to reset them, then it can be written one time again.

If HSE is selected as RTC clock: this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).

00: No clock (default after backup domain reset)

01: LSE clock used as RTC clock

10: LSI clock used as RTC clock

11: HSE clock divided by RTCPRE value is used as RTC clock

Bit 7 Reserved, must be kept at reset value.

**Bit 6 LSECSSD:** LSE clock security system failure detection

Set by hardware to indicate when a failure has been detected by the Clock Security System on the external 32 kHz oscillator.

- 0: No failure detected on 32 kHz oscillator (default after backup domain reset)
- 1: Failure detected on 32 kHz oscillator

**Bit 5 LSECSSON:** LSE clock security system enable

Set by software to enable the Clock Security System on 32 kHz oscillator.

LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after RTCSEL is selected.

Once enabled this bit cannot be disabled, except after a LSE failure detection (LSECSSD = '1'). In that case the software **must** disable LSECSSON.

- 0: Clock Security System on 32 kHz oscillator OFF (default after backup domain reset)
- 1: Clock Security System on 32 kHz oscillator ON

**Bits 4:3 LSEDRV[1:0]:** LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.

- 00: Lowest drive (default after backup domain reset)
- 01: Medium low drive
- 10: Medium high drive
- 11: Highest drive

**Bit 2 LSEBYP:** LSE oscillator bypass

Set and reset by software to bypass oscillator in debug mode. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = '1')

- 0: LSE oscillator not bypassed (default after backup domain reset)
- 1: LSE oscillator bypassed

**Bit 1 LSERDY:** LSE oscillator ready

Set and reset by hardware to indicate when the LSE is stable. This bit needs 6 cycles of **lse\_ck** clock to fall down after LSEON has been set to '0'.

- 0: LSE oscillator not ready (default after backup domain reset)
- 1: LSE oscillator ready

**Bit 0 LSEON:** LSE oscillator enabled

Set and reset by software.

- 0: LSE oscillator OFF (default after backup domain reset)
- 1: LSE oscillator ON

**8.7.25 RCC Clock Control and Status Register (RCC\_CSR)**

Address offset: 0x074

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LSIRDY	LSION
														r	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready

Set and reset by hardware to indicate when the Low Speed Internal RC oscillator is stable.

This bit needs 3 cycles of **lsi\_ck** clock to fall down after LSION has been set to '0'.

This bit can be set even when LSION is not enabled if there is a request for LSI clock by the Clock Security System on LSE or by the Low Speed Watchdog or by the RTC.

0: LSI clock is not ready (default after reset)

1: LSI clock is ready

Bit 0 **LSION**: LSI oscillator enable

Set and reset by software.

0: LSI is OFF (default after reset)

1: LSI is ON

### 8.7.26 RCC AHB3 Reset Register (RCC\_AHB3RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CPURST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDMMC1RST
rs															nw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	nw		nw							nw	nw				nw

Bit 31 **CPURST**: CPU reset

- Set by software, Reset by hardware
- 0: does not reset the CPU (default after reset)
- 1: resets the CPU, bit auto cleared to '0'.

Bits 30:17 Reserved, must be kept at reset value.

Bit 16 **SDMMC1RST**: SDMMC1 and SDMMC1 delay block reset

- Set and reset by software.
- 0: does not reset SDMMC1 and SDMMC1 Delay block (default after reset)
- 1: resets SDMMC1 and SDMMC1 Delay block

Bit 15 Reserved, must be kept at reset value.

Bit 14 **QSPIRST**: QUADSPI and QUADSPI delay block reset

- Set and reset by software.
- 0: does not reset QUADSPI and QUADSPI Delay block (default after reset)
- 1: resets QUADSPI and QUADSPI Delay block

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMC RST**: FMC block reset

- Set and reset by software.
- 0: does not reset FMC block (default after reset)
- 1: resets FMC block

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **JPGDECRST**: JPGDEC block reset

- Set and reset by software.
- 0: does not reset JPGDEC block (default after reset)
- 1: resets JPGDEC block

Bit 4 **DMA2DRST**: DMA2D block reset

Set and reset by software.

0: does not reset DMA2D block (default after reset)

1: resets DMA2D block

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MDMARST**: MDMA block reset

Set and reset by software.

0: does not reset MDMA block (default after reset)

1: resets MDMA block

### 8.7.27 RCC AHB1 Peripheral Reset Register(RCC\_AHB1RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	USB2OTGRST	Res.	USB1OTGRST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rW										rW				rW	rW

Bits 31:28 Reserved, must be kept at reset value.

- Bit 27 **USB2OTGRST**: USB2OTG block reset  
Set and reset by software.  
0: does not reset USB2OTG block (default after reset)  
1: resets USB2OTG block

Bit 26 Reserved, must be kept at reset value.

- Bit 25 **USB1OTGRST**: USB1OTG block reset  
Set and reset by software.  
0: does not reset USB1OTG block (default after reset)  
1: resets USB1OTG block

Bits 24:16 Reserved, must be kept at reset value.

- Bit 15 **ETH1MACRST**: ETH1MAC block reset  
Set and reset by software.  
0: does not reset ETH1MAC block (default after reset)  
1: resets ETH1MAC block

Bits 14:6 Reserved, must be kept at reset value.

- Bit 5 **ADC12RST**: ADC1&2 block reset  
Set and reset by software.  
0: does not reset ADC1&2 block (default after reset)  
1: resets ADC1&2 block

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2RST**: DMA2 block reset

Set and reset by software.

0: does not reset DMA2 block (default after reset)

1: resets DMA2 block

Bit 0 **DMA1RST**: DMA1 block reset

Set and reset by software.

0: does not reset DMA1 block (default after reset)

1: resets DMA1 block

### 8.7.28 RCC AHB2 Peripheral Reset Register (RCC\_AHB2RSTR)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	SDMMC2RST	Res.	Res.	RNGRST	HASHRST	CRYPTRST	Res.	Res.	Res.	CAMIFRST
						rw			rw	rw	rw				rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2RST**: SDMMC2 and SDMMC2 Delay block reset

Set and reset by software.

0: does not reset SDMMC2 and SDMMC2 Delay block (default after reset)

1: resets SDMMC2 and SDMMC2 Delay block

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **RNGRST**: Random Number Generator block reset

Set and reset by software.

0: does not reset RNG block (default after reset)

1: resets RNG block

Bit 5 **HASHRST**: Hash block reset

Set and reset by software.

0: does not reset hash block (default after reset)

1: resets hash block

Bit 4 **CRYPTRST**: Cryptography block reset

Set and reset by software.

0: does not reset cryptography block (default after reset)

1: resets cryptography block

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **CAMIFRST**: CAMITF block reset

Set and reset by software.

0: does not reset the CAMITF block (default after reset)

1: resets the CAMITF block

### 8.7.29 RCC AHB4 Peripheral Reset Register (RCC\_AHB4RSTR)

Address offset: 0x088

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	HSEMRST	ADC3RST	Res.	Res.	BDMARST	Res.	CRCRST	Res.	Res.	Res.
						rw	rw			rw		rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	GPIOKRST	GPIOJRST	GPIOIRST	GPIOHRST	GPIOGRST	GPIOFRST	GPIOERST	GPIODRST	GPIOCRST	GPIOBRST	GPIOARST
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

- Bit 25 **HSEMRST**: HSEM block reset  
Set and reset by software.  
0: does not reset the HSEM block (default after reset)  
1: resets the HSEM block

- Bit 24 **ADC3RST**: ADC3 block reset  
Set and reset by software.  
0: does not reset the ADC3 block (default after reset)  
1: resets the ADC3 block

Bits 23:22 Reserved, must be kept at reset value.

- Bit 21 **BDMARST**: BDMA block reset  
Set and reset by software.  
0: does not reset the BDMA block (default after reset)  
1: resets the BDMA block

Bit 20 Reserved, must be kept at reset value.

- Bit 19 **CRCRST**: CRC block reset  
Set and reset by software.  
0: does not reset the CRC block (default after reset)  
1: resets the CRC block

Bits 18:11 Reserved, must be kept at reset value.

- Bit 10 **GPIOKRST**: GPIOK block reset  
Set and reset by software.  
0: does not reset the GPIOK block (default after reset)  
1: resets the GPIOK block

- Bit 9 **GPIOJRST**: GPIOJ block reset  
Set and reset by software.  
0: does not reset the GPIOJ block (default after reset)  
1: resets the GPIOJ block

- Bit 8 **GPIORST**: GPIOI block reset  
Set and reset by software.  
0: does not reset the GPIOI block (default after reset)  
1: resets the GPIOI block
- Bit 7 **GPIOHRST**: GPIOH block reset  
Set and reset by software.  
0: does not reset the GPIOH block (default after reset)  
1: resets the GPIOH block
- Bit 6 **GPIOGRST**: GPIOG block reset  
Set and reset by software.  
0: does not reset the GPIOG block (default after reset)  
1: resets the GPIOG block
- Bit 5 **GPIOFRST**: GPIOF block reset  
Set and reset by software.  
0: does not reset the GPIOF block (default after reset)  
1: resets the GPIOF block
- Bit 4 **GPIOERST**: GPIOE block reset  
Set and reset by software.  
0: does not reset the GPIOE block (default after reset)  
1: resets the GPIOE block
- Bit 3 **GPIODRST**: GPIOD block reset  
Set and reset by software.  
0: does not reset the GPIOD block (default after reset)  
1: resets the GPIOD block
- Bit 2 **GPIOCRST**: GPIOC block reset  
Set and reset by software.  
0: does not reset the GPIOC block (default after reset)  
1: resets the GPIOC block
- Bit 1 **GPIOBRST**: GPIOB block reset  
Set and reset by software.  
0: does not reset the GPIOB block (default after reset)  
1: resets the GPIOB block
- Bit 0 **GPIOARST**: GPIOA block reset  
Set and reset by software.  
0: does not reset the GPIOA block (default after reset)  
1: resets the GPIOA block

**8.7.30 RCC APB3 Peripheral Reset Register (RCC\_APB3RSTR)**

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LTDCRST	Res.	Res.	Res.
												rw			

Bits 31:4 Reserved, must be kept at reset value.

- Bit 3 **LTDCRST**: LTDC block reset
  - Set and reset by software.
  - 0: does not reset the LTDC block (default after reset)
  - 1: resets the LTDC block

Bits 2:0 Reserved, must be kept at reset value.

### 8.7.31 RCC APB1 Peripheral Reset Register (RCC\_APB1LRSTR)

Address offset: 0x090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
USART8RST	USART7RST	DAC12RST	Res.	HDMICECRST	Res.	Res.	Res.	I2C3RST	I2C2RST	I2C1RST	UART5RST	UART4RST	USART3RST	USART2RST	SPDIFXRST

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPI3RST	SPI2RST	Res.	Res.	Res.	Res.	LPTIM1RST	TIM14RST	TIM13RST	TIM12RST	TIM7RST	TIM6RST	TIM5RST	TIM4RST	TIM3RST	TIM2RST
rW	rW					rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

- Bit 31 **USART8RST**: USART8 block reset  
Set and reset by software.  
0: does not reset the USART8 block (default after reset)  
1: resets the SWPMI USART8
- Bit 30 **USART7RST**: USART7 block reset  
Set and reset by software.  
0: does not reset the USART7 block (default after reset)  
1: resets the USART7 block
- Bit 29 **DAC12RST**: DAC1 and 2 Blocks Reset  
Set and reset by software.  
0: does not reset the DAC1&2 blocks (default after reset)  
1: resets the DAC1&2 blocks
- Bit 28 Reserved, must be kept at reset value.
- Bit 27 **HDMICECRST**: HDMI-CEC block reset  
Set and reset by software.  
0: does not reset the HDMI-CEC block (default after reset)  
1: resets the HDMI-CEC block
- Bits 26:24 Reserved, must be kept at reset value.
- Bit 23 **I2C3RST**: I2C3 block reset  
Set and reset by software.  
0: does not reset the I2C3 block (default after reset)  
1: resets the I2C3 block
- Bit 22 **I2C2RST**: I2C2 block reset  
Set and reset by software.  
0: does not reset the I2C2 block (default after reset)  
1: resets the I2C2 block

- Bit 21 **I2C1RST**: I2C1 block reset  
Set and reset by software.  
0: does not reset the I2C1 block (default after reset)  
1: resets the I2C1 block
- Bit 20 **UART5RST**: UART5 block reset  
Set and reset by software.  
0: does not reset the UART5 block (default after reset)  
1: resets the UART5 block
- Bit 19 **UART4RST**: UART4 block reset  
Set and reset by software.  
0: does not reset the UART4 block (default after reset)  
1: resets the UART4 block
- Bit 18 **USART3RST**: USART3 block reset  
Set and reset by software.  
0: does not reset the USART3 block (default after reset)  
1: resets the USART3 block
- Bit 17 **USART2RST**: USART2 block reset  
Set and reset by software.  
0: does not reset the USART2 block (default after reset)  
1: resets the USART2 block
- Bit 16 **SPDIFRXRST**: SPDIFRX block reset  
Set and reset by software.  
0: does not reset the SPDIFRX block (default after reset)  
1: resets the SPDIFRX block
- Bit 15 **SPI3RST**: SPI3 block reset  
Set and reset by software.  
0: does not reset the SPI3 block (default after reset)  
1: resets the SPI3 block
- Bit 14 **SPI2RST**: SPI2 block reset  
Set and reset by software.  
0: does not reset the SPI2 block (default after reset)  
1: resets the SPI2 block
- Bits 13:10 Reserved, must be kept at reset value.
- Bit 9 **LPTIM1RST**: LPTIM1 block reset  
Set and reset by software.  
0: does not reset the LPTIM1 block (default after reset)  
1: resets the LPTIM1 block
- Bit 8 **TIM14RST**: TIM14 block reset  
Set and reset by software.  
0: does not reset the TIM14 block (default after reset)  
1: resets the TIM14 block
- Bit 7 **TIM13RST**: TIM13 block reset  
Set and reset by software.  
0: does not reset the TIM13 block (default after reset)  
1: resets the TIM13 block

- Bit 6 **TIM12RST**: TIM12 block reset  
Set and reset by software.  
0: does not reset the TIM12 block (default after reset)  
1: resets the TIM12 block
- Bit 5 **TIM7RST**: TIM7 block reset  
Set and reset by software.  
0: does not reset the TIM7 block (default after reset)  
1: resets the TIM7 block
- Bit 4 **TIM6RST**: TIM6 block reset  
Set and reset by software.  
0: does not reset the TIM6 block (default after reset)  
1: resets the TIM6 block
- Bit 3 **TIM5RST**: TIM5 block reset  
Set and reset by software.  
0: does not reset the TIM5 block (default after reset)  
1: resets the TIM5 block
- Bit 2 **TIM4RST**: TIM4 block reset  
Set and reset by software.  
0: does not reset the TIM4 block (default after reset)  
1: resets the TIM4 block
- Bit 1 **TIM3RST**: TIM3 block reset  
Set and reset by software.  
0: does not reset the TIM3 block (default after reset)  
1: resets the TIM3 block
- Bit 0 **TIM2RST**: TIM2 block reset  
Set and reset by software.  
0: does not reset the TIM2 block (default after reset)  
1: resets the TIM2 block

### 8.7.32 RCC APB1 Peripheral Reset Register (RCC\_APB1HRSTR)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FDCANRST	Res.	Res.	MDIOSRST	OPAMPRST	Res.	SWPRST	CRSRST	Res.
							rw			rw	rw		rw	rw	

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FDCANRST**: FDCAN block reset

Set and reset by software.

0: does not reset the FDCAN block (default after reset)

1: resets the FDCAN block

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSRST**: MDIOS block reset

Set and reset by software.

0: does not reset the MDIOS block (default after reset)

1: resets the MDIOS block

Bit 4 **OPAMPRST**: OPAMP block reset

Set and reset by software.

0: does not reset the OPAMP block (default after reset)

1: resets the OPAMP block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWPRST**: SWPMI block reset

Set and reset by software.

0: does not reset the SWPMI block (default after reset)

1: resets the SWPMI block

Bit 1 **CRSRST**: Clock Recovery System reset

Set and reset by software.

0: does not reset CRS (default after reset)

1: resets CRS

Bit 0 Reserved, must be kept at reset value.

### 8.7.33 RCC APB2 Peripheral Reset Register (RCC\_APB2RSTR)

Address offset: 0x098

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	HRTMRST	DFSDM1RST	Res.	Res.	Res.	SAI3RST	SAI2RST	SAI1RST	Res.	SPI5RST	Res.	TIM17RST	TIM16RST	TIM15RST
		rw	rw				rw	rw	rw		rw		rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SPI4RST	SPI1RST	Res.	Res.	Res.	Res.	Res.	Res.	USART6RST	USART1RST	Res.	Res.	TIM8RST	TIM1RST
		rw	rw							rw	rw			rw	rw

Bits 31:30 Reserved, must be kept at reset value.

- Bit 29 **HRTMRST**: HRTIM block reset  
Set and reset by software.  
0: does not reset the HRTIM block (default after reset)  
1: resets the HRTIM block
- Bit 28 **DFSDM1RST**: DFSDM1 block reset  
Set and reset by software.  
0: does not reset DFSDM1 block (default after reset)  
1: resets DFSDM1 block

Bits 27:25 Reserved, must be kept at reset value.

- Bit 24 **SAI3RST**: SAI3 block reset  
Set and reset by software.  
0: does not reset the SAI3 block (default after reset)  
1: resets the SAI3 block
- Bit 23 **SAI2RST**: SAI2 block reset  
Set and reset by software.  
0: does not reset the SAI2 block (default after reset)  
1: resets the SAI2 block
- Bit 22 **SAI1RST**: SAI1 block reset  
Set and reset by software.  
0: does not reset the SAI1 (default after reset)  
1: resets the SAI1
- Bit 21 Reserved, must be kept at reset value.
- Bit 20 **SPI5RST**: SPI5 block reset  
Set and reset by software.  
0: does not reset the SPI5 block (default after reset)  
1: resets the SPI5 block
- Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM17RST**: TIM17 block reset  
Set and reset by software.  
0: does not reset the TIM17 block (default after reset)  
1: resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset  
Set and reset by software.  
0: does not reset the TIM16 block (default after reset)  
1: resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset  
Set and reset by software.  
0: does not reset the TIM15 block (default after reset)  
1: resets the TIM15 block

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 block reset  
Set and reset by software.  
0: does not reset the SPI4 block (default after reset)  
1: resets the SPI4 block

Bit 12 **SPI1RST**: SPI1 block reset  
Set and reset by software.  
0: does not reset the SPI1 block (default after reset)  
1: resets the SPI1 block

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **USART6RST**: USART6 block reset  
Set and reset by software.  
0: does not reset the USART6 block (default after reset)  
1: resets the USART6 block

Bit 4 **USART1RST**: USART1 block reset  
Set and reset by software.  
0: does not reset the USART1 block (default after reset)  
1: resets the USART1 block

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RST**: TIM8 block reset  
Set and reset by software.  
0: does not reset the TIM8 block (default after reset)  
1: resets the TIM8 block

Bit 0 **TIM1RST**: TIM1 block reset  
Set and reset by software.  
0: does not reset the TIM1 block (default after reset)  
1: resets the TIM1 block

### 8.7.34 RCC APB4 Peripheral Reset Register (RCC\_APB4RSTR)

Address offset: 0x09C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SAI4RST	Res.	Res.	Res.	Res.	Res.
										RW					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VREFRST	COMP12RST	Res.	LPTIM5RST	LPTIM4RST	LPTIM3RST	LPTIM2RST	Res.	I2C4RST	Res.	SPI6RST	Res.	LPUART1RST	Res.	SYSCFGRST	Res.
RW	RW		RW	RW	RW	RW		RW		RW		RW		RW	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:22 Reserved, must be kept at reset value.

- Bit 21 **SAI4RST**: SAI4 block reset  
Set and reset by software.  
0: does not reset the SAI4 block (default after reset)  
1: resets the SAI4 block

Bits 20:16 Reserved, must be kept at reset value.

- Bit 15 **VREFRST**: VREF block reset  
Set and reset by software.  
0: does not reset the VREF block (default after reset)  
1: resets the VREF block
- Bit 14 **COMP12RST**: COMP12 Blocks Reset  
Set and reset by software.  
0: does not reset the COMP1&2 blocks (default after reset)  
1: resets the COMP1&2 blocks
- Bit 13 Reserved, must be kept at reset value.
- Bit 12 **LPTIM5RST**: LPTIM5 block reset  
Set and reset by software.  
0: does not reset the LPTIM5 block (default after reset)  
1: resets the LPTIM5 block
- Bit 11 **LPTIM4RST**: LPTIM4 block reset  
Set and reset by software.  
0: does not reset the LPTIM4 block (default after reset)  
1: resets the LPTIM4 block
- Bit 10 **LPTIM3RST**: LPTIM3 block reset  
Set and reset by software.  
0: does not reset the LPTIM3 block (default after reset)  
1: resets the LPTIM3 block

- Bit 9 **LPTIM2RST**: LPTIM2 block reset  
Set and reset by software.  
0: does not reset the LPTIM2 block (default after reset)  
1: resets the LPTIM2 block
- Bit 8 Reserved, must be kept at reset value.
- Bit 7 **I2C4RST**: I2C4 block reset  
Set and reset by software.  
0: does not reset the I2C4 block (default after reset)  
1: resets the I2C4 block
- Bit 6 Reserved, must be kept at reset value.
- Bit 5 **SPI6RST**: SPI6 block reset  
Set and reset by software.  
0: does not reset the SPI6 block (default after reset)  
1: resets the SPI6 block
- Bit 4 Reserved, must be kept at reset value.
- Bit 3 **LPUART1RST**: LPUART1 block reset  
Set and reset by software.  
0: does not reset the LPUART1 block (default after reset)  
1: resets the LPUART1 block
- Bit 2 Reserved, must be kept at reset value.
- Bit 1 **SYSCFGRST**: SYSCFG block reset  
Set and reset by software.  
0: does not reset the SYSCFG block (default after reset)  
1: resets the SYSCFG block
- Bit 0 Reserved, must be kept at reset value.

### 8.7.35 RCC Global Control Register (RCC\_GCR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WW1RSC
															rw1

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **WW1RSC**: WWDG1 reset scope control

This bit can be set by software but is cleared by hardware during a system reset  
 In order to work properly, before enabling the WWDG1, this bit must be set to '1'.

### 8.7.36 RCC D3 Autonomous mode Register (RCC\_D3AMR)

The Autonomous mode allows providing the peripheral clocks to peripherals located in D3, even if the CPU is in CStop mode. When a peripheral is enabled, and has its autonomous bit enabled, it receives its peripheral clocks according to D3 domain state, if the CPU is in CStop mode.

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SRAM4AMEN	BKPRAMAMEN	Res.	Res.	Res.	ADC3AMEN	Res.	Res.	SAI4AMEN	Res.	CRCAMEN	Res.	Res.	RTCAMEN
		rw	rw				rw			rw		rw			rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VREFAMEN	COMP12AMEN	Res.	LPTIM3AMEN	LPTIM4AMEN	LPTIM3AMEN	LPTIM2AMEN	Res.	I2C4AMEN	Res.	SPI6AMEN	Res.	LPUART1AMEN	Res.	Res.	BDMAAMEN
rw	rw		rw	rw	rw	rw		rw		rw		rw			rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **SRAM4AMEN**: SRAM4 Autonomous mode enable

Set and reset by software.

0: SRAM4 clock is disabled when the CPU is in CStop (default after reset)

1: SRAM4 peripheral bus clock enabled when D3 domain is in DRun.

Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information

Bit 28 **BKPSRAMAMEN**: Backup RAM Autonomous mode enable

Set and reset by software.

0: Backup RAM clock is disabled when the CPU is in CStop (default after reset)

1: Backup RAM clock enabling is controlled by D3 domain state.

Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information

Bit 27 Reserved, must be kept at reset value.

Bits 26:25 Reserved, must be kept at reset value.

Bit 24 **ADC3AMEN**: ADC3 Autonomous mode enable

Set and reset by software.

0: ADC3 peripheral clocks are disabled when the CPU is in CStop (default after reset)

1: ADC3 peripheral clocks enabled when D3 domain is in DRun.

Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **SAI4AMEN**: SAI4 Autonomous mode enable

Set and reset by software.

0: SAI4 peripheral clocks are disabled when the CPU is in CStop (default after reset)

1: SAI4 peripheral clocks enabled when D3 domain is in DRun.

Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information

Bit 20 Reserved, must be kept at reset value.

- Bit 19 **CRCAMEN**: CRC Autonomous mode enable  
Set and reset by software.  
0: CRC peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: CRC peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bits 18:17 Reserved, must be kept at reset value.
- Bit 16 **RTCAMEN**: RTC Autonomous mode enable  
Set and reset by software.  
0: RTC peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: RTC peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 15 **VREFAMEN**: VREF Autonomous mode enable  
Set and reset by software.  
0: VREF peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: VREF peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 14 **COMP12AMEN**: COMP12 Autonomous mode enable  
Set and reset by software.  
0: COMP12 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: COMP12 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 13 Reserved, must be kept at reset value.
- Bit 12 **LPTIM5AMEN**: LPTIM5 Autonomous mode enable  
Set and reset by software.  
0: LPTIM5 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM5 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 11 **LPTIM4AMEN**: LPTIM4 Autonomous mode enable  
Set and reset by software.  
0: LPTIM4 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM4 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 10 **LPTIM3AMEN**: LPTIM3 Autonomous mode enable  
Set and reset by software.  
0: LPTIM3 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM3 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 9 **LPTIM2AMEN**: LPTIM2 Autonomous mode enable  
Set and reset by software.  
0: LPTIM2 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM2 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 8 Reserved, must be kept at reset value.
- Bit 7 **I2C4AMEN**: I2C4 Autonomous mode enable  
Set and reset by software.  
0: I2C4 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: I2C4 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information

- Bit 6 Reserved, must be kept at reset value.
- Bit 5 **SPI6AMEN**: SPI6 Autonomous mode enable  
Set and reset by software.  
0: SPI6 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: SPI6 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bit 4 Reserved, must be kept at reset value.
- Bit 3 **LPUART1AMEN**: LPUART1 Autonomous mode enable  
Set and reset by software.  
0: LPUART1 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPUART1 peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information
- Bits 2:1 Reserved, must be kept at reset value.
- Bit 0 **BDMAAMEN**: BDMA and DMAMUX Autonomous mode enable  
Set and reset by software.  
0: BDMA and DMAMUX peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: BDMA and DMAMUX peripheral clocks enabled when D3 domain is in DRun.  
Refer to [Section 8.5.11: Peripheral clock gating control](#) for additional information

### 8.7.37 RCC Reset Status Register (RCC\_RSR)

This register can be accessed via two different offset address.

**Table 56. RCC\_RSR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_RSR	0x0D0	0x00FE 0000 <sup>(1)</sup>
RCC_C1_RSR	0x130	

1. Reset by power-on reset only

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	LPWRRSTF	Res.	WWDG1RSTF	Res.	IWDG1RSTF	Res.	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	D2RSTF	D1RSTF	Res.	CPURSTF	RMVF
	r		r		r		r	r	r	r	r	r		r	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **LPWRRSTF**: Reset due to illegal D1 DStandby or CPU CStop flag <sup>(1)</sup>

Reset by software by writing the RMVF bit.

Set by hardware when D1 domain goes erroneously in DStandby or when CPU goes erroneously in CStop.

0: No illegal reset occurred (default after power-on reset)

1: Illegal D1 DStandby or CPU CStop reset occurred

Bit 29 Reserved, must be kept at reset value.

Bit 28 **WWDG1RSTF**: Window Watchdog reset flag <sup>(1)</sup>

Reset by software by writing the RMVF bit.

Set by hardware when a window watchdog reset occurs.

0: No window watchdog reset occurred from WWDG1 (default after power-on reset)

1: window watchdog reset occurred from WWDG1

Bit 27 Reserved, must be kept at reset value.

Bit 26 **IWDG1RSTF**: Independent Watchdog reset flag <sup>(1)</sup>

Reset by software by writing the RMVF bit.

Set by hardware when an independent watchdog reset occurs.

0: No independent watchdog reset occurred (default after power-on reset)

1: Independent watchdog reset occurred

Bit 25 Reserved, must be kept at reset value.

- Bit 24 **SFTRSTF**: System reset from CPU reset flag <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware when the system reset is due to CPU. The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the CM7.  
0: No CPU software reset occurred (default after power-on reset)  
1: A system reset has been generated by the CPU
- Bit 23 **PORRSTF**: POR/PDR reset flag <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware when a POR/PDR reset occurs.  
0: No POR/PDR reset occurred  
1: POR/PDR reset occurred (default after power-on reset)
- Bit 22 **PINRSTF**: Pin reset flag (NRST) <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware when a reset from pin occurs.  
0: No reset from pin occurred  
1: Reset from pin occurred (default after power-on reset)
- Bit 21 **BORRSTF**: BOR reset flag <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware when a BOR reset occurs (**pwr\_bor\_rst**).  
0: No BOR reset occurred  
1: BOR reset occurred (default after power-on reset)
- Bit 20 **D2RSTF**: D2 domain power switch reset flag <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware when a D2 domain exits from DStandby or after of power-on reset. Refer to [Table 47](#) for details.  
0: No D2 domain power switch reset occurred  
1: A D2 domain power switch (ePOD2) reset occurred (default after power-on reset)
- Bit 19 **D1RSTF**: D1 domain power switch reset flag <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware when a D1 domain exits from DStandby or after of power-on reset. Refer to [Table 47](#) for details.  
0: No D1 domain power switch reset occurred  
1: A D1 domain power switch (ePOD1) reset occurred (default after power-on reset)
- Bit 18 Reserved, must be kept at reset value.
- Bit 17 **CPURSTF**: CPU reset flag <sup>(1)</sup>  
Reset by software by writing the RMVF bit.  
Set by hardware every time a CPU reset occurs.  
0: No CPU reset occurred  
1: A CPU reset occurred (default after power-on reset)
- Bit 16 **RMVF**: Remove reset flag  
Set and reset by software to reset the value of the reset flags.  
0: Reset of the reset flags not activated (default after power-on reset)  
1: Reset the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

1. Refer to [Table 47: Reset source identification \(RCC\\_RSR\)](#) for details on flag behavior.

### 8.7.38 RCC AHB3 Clock Register (RCC\_AHB3ENR)

This register can be accessed via two different offset address.

**Table 57. RCC\_AHB3ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB3ENR	0x0D4	0x0000 0000
RCC_C1_AHB3ENR	0x134	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDMMC1EN
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	QSPIEN	Res.	FMCEN	Res.	Res.	Res.	Res.	Res.	Res.	JPGDECEN	DMA2DEN	Res.	Res.	Res.	MDMAEN
	rw		rw							rw	rw				rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SDMMC1EN**: SDMMC1 and SDMMC1 Delay Clock Enable

Set and reset by software.

0: SDMMC1 and SDMMC1 Delay clock disabled (default after reset)

1: SDMMC1 and SDMMC1 Delay clock enabled

Bit 15 Reserved, must be kept at reset value.

Bit 14 **QSPIEN**: QUADSPI and QUADSPI Delay Clock Enable

Set and reset by software.

0: QUADSPI and QUADSPI Delay clock disabled (default after reset)

1: QUADSPI and QUADSPI Delay clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCEN**: FMC Peripheral Clocks Enable

Set and reset by software.

0: FMC peripheral clocks disabled (default after reset)

1: FMC peripheral clocks enabled

The peripheral clocks of the FMC are: the kernel clock selected by FMCSEL and provided to `fmc_ker_ck` input, and the `rcc_hclk3` bus interface clock.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **JPGDECEN**: JPGDEC Peripheral Clock Enable

Set and reset by software.

0: JPGDEC peripheral clock disabled (default after reset)

1: JPGDEC peripheral clock enabled

Bit 4 **DMA2DEN**: DMA2D Peripheral Clock Enable

Set and reset by software.

0: DMA2D peripheral clock disabled (default after reset)

1: DMA2D peripheral clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MDMAEN**: MDMA Peripheral Clock Enable

Set and reset by software.

0: MDMA peripheral clock disabled (default after reset)

1: MDMA peripheral clock enabled

### 8.7.39 RCC AHB1 Clock Register (RCC\_AHB1ENR)

This register can be accessed via two different offset address.

**Table 58. RCC\_AHB1ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB1ENR	0x0D8	0x0000 0000
RCC_C1_AHB1ENR	0x138	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	USB2ULPIEN	USB2OTGEN	USB1ULPIEN	USB1OTGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ETH1RXEN	ETH1TXEN
			r/w	r/w	r/w	r/w								r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETH1MACEEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADC12EN	Res.	Res.	Res.	DMA2EN	DMA1EN
r/w										r/w				r/w	r/w

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **USB2ULPIEN**: USB\_PHY2 Clocks Enable  
 Set and reset by software.  
 0: USB\_PHY2 clocks disabled (default after reset)  
 1: USB\_PHY2 clocks enabled

Bit 27 **USB2OTGEN**: USB2OTG Peripheral Clocks Enable  
 Set and reset by software.  
 0: USB2OTG peripheral clocks disabled (default after reset)  
 1: USB2OTG peripheral clocks enabled  
 The peripheral clocks of the USB2OTG are: the kernel clock selected by USBSEL and the **rcc\_hclk1** bus interface clock.

Bit 26 **USB1ULPIEN**: USB\_PHY1 Clocks Enable  
 Set and reset by software.  
 0: USB1ULPI PHY clocks disabled (default after reset)  
 1: USB1ULPI PHY clocks enabled

Bit 25 **USB1OTGEN**: USB1OTG Peripheral Clocks Enable  
 Set and reset by software.  
 0: USB1OTG peripheral clocks disabled (default after reset)  
 1: USB1OTG peripheral clocks enabled  
 The peripheral clocks of the USB1OTG are: the kernel clock selected by USBSEL and the **rcc\_hclk1** bus interface clock.

Bits 24:18 Reserved, must be kept at reset value.

Bit 17 **ETH1RXEN**: Ethernet Reception Clock Enable

Set and reset by software.

0: Ethernet Reception clock disabled (default after reset)

1: Ethernet Reception clock enabled

Bit 16 **ETH1TXEN**: Ethernet Transmission Clock Enable

Set and reset by software.

0: Ethernet Transmission clock disabled (default after reset)

1: Ethernet Transmission clock enabled

Bit 15 **ETH1MACEN**: Ethernet MAC bus interface Clock Enable

Set and reset by software.

0: Ethernet MAC bus interface clock disabled (default after reset)

1: Ethernet MAC bus interface clock enabled

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12EN**: ADC1/2 Peripheral Clocks Enable

Set and reset by software.

0: ADC1 and 2 peripheral clocks disabled (default after reset)

1: ADC1 and 2 peripheral clocks enabled

The peripheral clocks of the ADC1&2 are: the kernel clock selected by ADCSEL and provided to `adc_ker_ck` input, and the `rcc_hclk1` bus interface clock.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2EN**: DMA2 Clock Enable

Set and reset by software.

0: DMA2 clock disabled (default after reset)

1: DMA2 clock enabled

Bit 0 **DMA1EN**: DMA1 Clock Enable

Set and reset by software.

0: DMA1 clock disabled (default after reset)

1: DMA1 clock enabled

### 8.7.40 RCC AHB2 Clock Register (RCC\_AHB2ENR)

This register can be accessed via two different offset address.

**Table 59. RCC\_AHB2ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB2ENR	0x0DC	0x0000 0000
RCC_C1_AHB2ENR	0x13C	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRAM3EN	SRAM2EN	SRAM1EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	SDMMC2EN	Res.	Res.	RNGEN	HASHEN	CRYPTEN	Res.	Res.	Res.	DCMIEN
						rw			rw	rw	rw				rw

**Bit 31 SRAM3EN:** SRAM3 block enable

Set and reset by software.

When set, this bit indicates that the SRAM3 is allocated by the CPU. It causes the D2 domain to take into account also the CPU operation modes, i.e. keeping D2 domain in DRun when the CPU is in CRun.

- 0: SRAM3 interface clock is disabled. (default after reset)
- 1: SRAM3 interface clock is enabled.

**Bit 30 SRAM2EN:** SRAM2 block enable

Set and reset by software.

When set, this bit indicates that the SRAM2 is allocated by the CPU. It causes the D2 domain to take into account also the CPU operation modes, i.e. keeping D2 domain in DRun when the CPU is in CRun.

- 0: SRAM2 interface clock is disabled. (default after reset)
- 1: SRAM2 interface clock is enabled.

**Bit 29 SRAM1EN:** SRAM1 block enable

Set and reset by software.

When set, this bit indicates that the SRAM1 is allocated by the CPU. It causes the D2 domain to take into account also the CPU operation modes, i.e. keeping D2 domain in DRun when the CPU is in CRun.

- 0: SRAM1 interface clock is disabled. (default after reset)
- 1: SRAM1 interface clock is enabled.

Bits 28:10 Reserved, must be kept at reset value.

**Bit 9 SDMMC2EN:** SDMMC2 and SDMMC2 delay clock enable

Set and reset by software.

- 0: SDMMC2 and SDMMC2 Delay clock disabled (default after reset)
- 1: SDMMC2 and SDMMC2 Delay clock enabled

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **RNGEN**: RNG peripheral clocks enable

Set and reset by software.

0: RNG peripheral clocks disabled (default after reset)

1: RNG peripheral clocks enabled:

The peripheral clocks of the RNG are: the kernel clock selected by RNGSEL and provided to **rng\_ker\_ck** input, and the **rcc\_hclk2** bus interface clock.

Bit 5 **HASHEN**: HASH peripheral clock enable

Set and reset by software.

0: HASH peripheral clock disabled (default after reset)

1: HASH peripheral clock enabled

Bit 4 **CRYPTEN**: CRYPT peripheral clock enable

Set and reset by software.

0: CRYPT peripheral clock disabled (default after reset)

1: CRYPT peripheral clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIEN**: DCMI peripheral clock enable

Set and reset by software.

0: DCMI peripheral clock disabled (default after reset)

1: DCMI peripheral clock enabled

### 8.7.41 RCC AHB4 Clock Register (RCC\_AHB4ENR)

This register can be accessed via two different offset address.

**Table 60. RCC\_AHB4ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB4ENR	0x0E0	0x0000 0000
RCC_C1_AHB4ENR	0x140	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	BKPRAMEN	Res.	Res.	HSEMEN	ADC3EN	Res.	Res.	BDMAEN	Res.	CRCEN	Res.	Res.	Res.
			rw			rw	rw			rw		rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	GPIOKEN	GPIOJEN	GPIOJEN	GPIOHEN	GPIOGEN	GPIOFEN	GPIOEN	GPIODEN	GPIOCEN	GPIOBEN	GPIOAEN
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

- Bit 28 **BKPRAMEN**: Backup RAM Clock Enable  
Set and reset by software.  
0: Backup RAM clock disabled (default after reset)  
1: Backup RAM clock enabled

Bits 27:26 Reserved, must be kept at reset value.

- Bit 25 **HSEMEN**: HSEM peripheral clock enable  
Set and reset by software.  
0: HSEM peripheral clock disabled (default after reset)  
1: HSEM peripheral clock enabled

- Bit 24 **ADC3EN**: ADC3 Peripheral Clocks Enable  
Set and reset by software.  
0: ADC3 peripheral clocks disabled (default after reset)  
1: ADC3 peripheral clocks enabled  
The peripheral clocks of the ADC3 are: the kernel clock selected by ADCSEL and provided to `adc_ker_ck` input, and the `rcc_hclk4` bus interface clock.

Bits 23:22 Reserved, must be kept at reset value.

- Bit 21 **BDMAEN**: BDMA and DMAMUX2 Clock Enable  
Set and reset by software.  
0: BDMA and DMAMUX2 clock disabled (default after reset)  
1: BDMA and DMAMUX2 clock enabled

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CRCCEN**: CRC peripheral clock enable  
Set and reset by software.  
0: CRC peripheral clock disabled (default after reset)  
1: CRC peripheral clock enabled

Bits 18:11 Reserved, must be kept at reset value.

Bit 10 **GPIOKEN**: GPIOK peripheral clock enable  
Set and reset by software.  
0: GPIOK peripheral clock disabled (default after reset)  
1: GPIOK peripheral clock enabled

Bit 9 **GPIOJEN**: GPIOJ peripheral clock enable  
Set and reset by software.  
0: GPIOJ peripheral clock disabled (default after reset)  
1: GPIOJ peripheral clock enabled

Bit 8 **GPIOIEN**: GPIOI peripheral clock enable  
Set and reset by software.  
0: GPIOI peripheral clock disabled (default after reset)  
1: GPIOI peripheral clock enabled

Bit 7 **GPIOHEN**: GPIOH peripheral clock enable  
Set and reset by software.  
0: GPIOH peripheral clock disabled (default after reset)  
1: GPIOH peripheral clock enabled

Bit 6 **GPIOGEN**: GPIOG peripheral clock enable  
Set and reset by software.  
0: GPIOG peripheral clock disabled (default after reset)  
1: GPIOG peripheral clock enabled

Bit 5 **GPIOFEN**: GPIOF peripheral clock enable  
Set and reset by software.  
0: GPIOF peripheral clock disabled (default after reset)  
1: GPIOF peripheral clock enabled

Bit 4 **GPIOEEN**: GPIOE peripheral clock enable  
Set and reset by software.  
0: GPIOE peripheral clock disabled (default after reset)  
1: GPIOE peripheral clock enabled

Bit 3 **GPIODEN**: GPIOD peripheral clock enable  
Set and reset by software.  
0: GPIOD peripheral clock disabled (default after reset)  
1: GPIOD peripheral clock enabled

- Bit 2 **GPIOCEN**: GPIOC peripheral clock enable  
Set and reset by software.  
0: GPIOC peripheral clock disabled (default after reset)  
1: GPIOC peripheral clock enabled
- Bit 1 **GPIOBEN**: GPIOB peripheral clock enable  
Set and reset by software.  
0: GPIOB peripheral clock disabled (default after reset)  
1: GPIOB peripheral clock enabled
- Bit 0 **GPIOAEN**: GPIOA peripheral clock enable  
Set and reset by software.  
0: GPIOA peripheral clock disabled (default after reset)  
1: GPIOA peripheral clock enabled

8.7.42 RCC APB3 Clock Register (RCC\_APB3ENR)

This register can be accessed via two different offset address.

Table 61. RCC\_APB3ENR address offset and reset value

Register Name	Address Offset	Reset Value
RCC_APB3ENR	0x0E4	0x0000 0000
RCC_C1_APB3ENR	0x144	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WWDG1EN	Res.	Res.	LTDGEN	Res.	Res.	Res.
									rs			rw			

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **WWDG1EN**: WWDG1 Clock Enable

Set by software, and reset by hardware when a system reset occurs.

Note that in order to work properly, before enabling the WWDG1, the bit WW1RSC must be set to '1'.

0: WWDG1 peripheral clock disable (default after reset)

1: WWDG1 peripheral clock enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **LTDGEN**: LTDC peripheral clock enable

Provides the pixel clock (**ltdc\_ker\_ck**) to the LTDC block.

Set and reset by software.

0: LTDC peripheral clock disabled (default after reset)

1: LTDC peripheral clock provided to the LTDC block

Bits 2:0 Reserved, must be kept at reset value.

### 8.7.43 RCC APB1 Clock Register (RCC\_APB1LENR)

This register can be accessed via two different offset address.

**Table 62. RCC\_APB1ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB1LENR	0x0E8	0x0000 0000
RCC_C1_APB1LENR	0x148	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
USART8EN	USART7EN	DAC12EN	Res.	HDMICECEN	Res.	Res.	Res.	I2C3EN	I2C2EN	I2C1EN	UART5EN	UART4EN	USART3EN	USART2EN	SPDIFRXEN
rw	rw	rw		rw				rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPI3EN	SPI2EN	Res.	Res.	Res.	Res.	LPTIM1EN	TIM14EN	TIM13EN	TIM12EN	TIM7EN	TIM6EN	TIM5EN	TIM4EN	TIM3EN	TIM2EN
rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

**Bit 31 USART8EN:** USART8 Peripheral Clocks Enable

Set and reset by software.

0: USART8 peripheral clocks disable (default after reset)

1: USART8 peripheral clocks enabled

The peripheral clocks of the USART8 are: the kernel clock selected by USART234578SEL and provided to usart\_ker\_ck input, and the **rcc\_pclk1** bus interface clock.

**Bit 30 USART7EN:** USART7 Peripheral Clocks Enable

Set and reset by software.

0: USART7 peripheral clocks disable (default after reset)

1: USART7 peripheral clocks enabled

The peripheral clocks of the USART7 are: the kernel clock selected by USART234578SEL and provided to usart\_ker\_ck input, and the **rcc\_pclk1** bus interface clock.

**Bit 29 DAC12EN:** DAC1&2 peripheral clock enable

Set and reset by software.

0: DAC1&2 peripheral clock disable (default after reset)

1: DAC1&2 peripheral clock enabled

**Bit 28** Reserved, must be kept at reset value.

**Bit 27 HDMICECEN:** HDMI-CEC peripheral clock enable

Set and reset by software.

0: HDMI-CEC peripheral clock disable (default after reset)

1: HDMI-CEC peripheral clock enabled

The peripheral clocks of the HDMI-CEC are: the kernel clock selected by CECSEL and provided to **cec\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bits 26:24 Reserved, must be kept at reset value.

- Bit 23 **I2C3EN**: I2C3 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C3 peripheral clocks disable (default after reset)  
1: I2C3 peripheral clocks enabled  
The peripheral clocks of the I2C3 are: the kernel clock selected by I2C123SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 22 **I2C2EN**: I2C2 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C2 peripheral clocks disable (default after reset)  
1: I2C2 peripheral clocks enabled  
The peripheral clocks of the I2C2 are: the kernel clock selected by I2C123SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 21 **I2C1EN**: I2C1 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C1 peripheral clocks disable (default after reset)  
1: I2C1 peripheral clocks enabled  
The peripheral clocks of the I2C1 are: the kernel clock selected by I2C123SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 20 **UART5EN**: UART5 Peripheral Clocks Enable  
Set and reset by software.  
0: UART5 peripheral clocks disable (default after reset)  
1: UART5 peripheral clocks enabled  
The peripheral clocks of the UART5 are: the kernel clock selected by USART234578SEL and provided to **uart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 19 **UART4EN**: UART4 Peripheral Clocks Enable  
Set and reset by software.  
0: UART4 peripheral clocks disable (default after reset)  
1: UART4 peripheral clocks enabled  
The peripheral clocks of the UART4 are: the kernel clock selected by USART234578SEL and provided to **uart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 18 **USART3EN**: USART3 Peripheral Clocks Enable  
Set and reset by software.  
0: USART3 peripheral clocks disable (default after reset)  
1: USART3 peripheral clocks enabled  
The peripheral clocks of the USART3 are: the kernel clock selected by USART234578SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 17 **USART2EN**: USART2 Peripheral Clocks Enable  
Set and reset by software.  
0: USART2 peripheral clocks disable (default after reset)  
1: USART2 peripheral clocks enabled  
The peripheral clocks of the USART2 are: the kernel clock selected by USART234578SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 16 **SPDIFRXEN**: SPDIFRX Peripheral Clocks Enable  
Set and reset by software.  
0: SPDIFRX peripheral clocks disable (default after reset)  
1: SPDIFRX peripheral clocks enabled  
The peripheral clocks of the SPDIFRX are: the kernel clock selected by SPDIFSEL and provided to **spdifrx\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 15 **SPI3EN**: SPI3 Peripheral Clocks Enable

Set and reset by software.

0: SPI3 peripheral clocks disable (default after reset)

1: SPI3 peripheral clocks enabled

The peripheral clocks of the SPI3 are: the kernel clock selected by I2S123SRC and provided to **spi\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 14 **SPI2EN**: SPI2 Peripheral Clocks Enable

Set and reset by software.

0: SPI2 peripheral clocks disable (default after reset)

1: SPI2 peripheral clocks enabled

The peripheral clocks of the SPI2 are: the kernel clock selected by I2S123SRC and provided to **spi\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 Peripheral Clocks Enable

Set and reset by software.

0: LPTIM1 peripheral clocks disable (default after reset)

1: LPTIM1 peripheral clocks enabled

The peripheral clocks of the LPTIM1 are: the kernel clock selected by LPTIM1SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 8 **TIM14EN**: TIM14 peripheral clock enable

Set and reset by software.

0: TIM14 peripheral clock disable (default after reset)

1: TIM14 peripheral clock enabled

Bit 7 **TIM13EN**: TIM13 peripheral clock enable

Set and reset by software.

0: TIM13 peripheral clock disable (default after reset)

1: TIM13 peripheral clock enabled

Bit 6 **TIM12EN**: TIM12 peripheral clock enable

Set and reset by software.

0: TIM12 peripheral clock disable (default after reset)

1: TIM12 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 peripheral clock enable

Set and reset by software.

0: TIM7 peripheral clock disable (default after reset)

1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 peripheral clock enable

Set and reset by software.

0: TIM6 peripheral clock disable (default after reset)

1: TIM6 peripheral clock enabled

Bit 3 **TIM5EN**: TIM5 peripheral clock enable

Set and reset by software.

0: TIM5 peripheral clock disable (default after reset)

1: TIM5 peripheral clock enabled

- Bit 2 **TIM4EN**: TIM4 peripheral clock enable  
Set and reset by software.  
0: TIM4 peripheral clock disable (default after reset)  
1: TIM4 peripheral clock enabled
- Bit 1 **TIM3EN**: TIM3 peripheral clock enable  
Set and reset by software.  
0: TIM3 peripheral clock disable (default after reset)  
1: TIM3 peripheral clock enabled
- Bit 0 **TIM2EN**: TIM2 peripheral clock enable  
Set and reset by software.  
0: TIM2 peripheral clock disable (default after reset)  
1: TIM2 peripheral clock enabled

### 8.7.44 RCC APB1 Clock Register (RCC\_APB1HENR)

This register can be accessed via two different offset address.

**Table 63. RCC\_APB1ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB1HENR	0x0EC	0x0000 0000
RCC_C1_APB1HENR	0x14C	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FDCANEN	Res.	Res.	MDIOSEN	OPAMPEN	Res.	SWPEN	CRSEN	Res.
							rw			rw	rw		rw	rw	

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FDCANEN**: FDCAN Peripheral Clocks Enable

Set and reset by software.

0: FDCAN peripheral clocks disable (default after reset)

1: FDCAN peripheral clocks enabled:

The peripheral clocks of the FDCAN are: the kernel clock selected by FDCANSEL and provided to **fdcan\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSEN**: MDIOS peripheral clock enable

Set and reset by software.

0: MDIOS peripheral clock disable (default after reset)

1: MDIOS peripheral clock enabled

Bit 4 **OPAMPEN**: OPAMP peripheral clock enable

Set and reset by software.

0: OPAMP peripheral clock disable (default after reset)

1: OPAMP peripheral clock enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWPEN**: SWPMI Peripheral Clocks Enable

Set and reset by software.

0: SWPMI peripheral clocks disable (default after reset)

1: SWPMI peripheral clocks enabled:

The peripheral clocks of the SWPMI are: the kernel clock selected by SWPSEL and provided to **swpmi\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 1 **CRSEN**: Clock Recovery System peripheral clock enable

Set and reset by software.

0: CRS peripheral clock disable (default after reset)

1: CRS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

### 8.7.45 RCC APB2 Clock Register (RCC\_APB2ENR)

This register can be accessed via two different offset address.

**Table 64. RCC\_APB2ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB2ENR	0x0F0	0x0000 0000
RCC_C1_APB2ENR	0x150	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	HRTIMEN	DFSDM1EN	Res.	Res.	Res.	SAI3EN	SAI2EN	SAI1EN	Res.	SPI5EN	Res.	TIM17EN	TIM16EN	TIM15EN
		rw	rw				rw	rw	rw		rw		rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SPI4EN	SPI1EN	Res.	Res.	Res.	Res.	Res.	Res.	USART6EN	USART1EN	Res.	Res.	TIM8EN	TIM1EN
		rw	rw							rw	rw			rw	rw

Bits 31:30 Reserved, must be kept at reset value.

- Bit 29 **HRTIMEN**: HRTIM peripheral clock enable  
Set and reset by software.  
0: HRTIM peripheral clock disabled (default after reset)  
1: HRTIM peripheral clock enabled

- Bit 28 **DFSDM1EN**: DFSDM1 Peripheral Clocks Enable  
Set and reset by software.  
0: DFSDM1 peripheral clocks disabled (default after reset)  
1: DFSDM1 peripheral clocks enabled  
DFSDM1 peripheral clocks are: the kernel clocks selected by SAI1SEL and DFSDM1SEL and provided to **Aclk** and **clk** inputs respectively, and the **rcc\_pclk2** bus interface clock.

Bits 27:25 Reserved, must be kept at reset value.

- Bit 24 **SAI3EN**: SAI3 Peripheral Clocks Enable  
Set and reset by software.  
0: SAI3 peripheral clocks disabled (default after reset)  
1: SAI3 peripheral clocks enabled  
The peripheral clocks of the SAI3 are: the kernel clock selected by SAI23SEL and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.

- Bit 23 **SAI2EN**: SAI2 Peripheral Clocks Enable  
Set and reset by software.  
0: SAI2 peripheral clocks disabled (default after reset)  
1: SAI2 peripheral clocks enabled  
The peripheral clocks of the SAI2 are: the kernel clock selected by SAI23SEL and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.

- Bit 22 **SAI1EN**: SAI1 Peripheral Clocks Enable  
Set and reset by software.  
0: SAI1 peripheral clocks disabled (default after reset)  
1: SAI1 peripheral clocks enabled:  
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.
- Bit 21 Reserved, must be kept at reset value.
- Bit 20 **SPI5EN**: SPI5 Peripheral Clocks Enable  
Set and reset by software.  
0: SPI5 peripheral clocks disabled (default after reset)  
1: SPI5 peripheral clocks enabled:  
The peripheral clocks of the SPI5 are: the kernel clock selected by SPI45SEL and provided to **spi\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.
- Bit 19 Reserved, must be kept at reset value.
- Bit 18 **TIM17EN**: TIM17 peripheral clock enable  
Set and reset by software.  
0: TIM17 peripheral clock disabled (default after reset)  
1: TIM17 peripheral clock enabled
- Bit 17 **TIM16EN**: TIM16 peripheral clock enable  
Set and reset by software.  
0: TIM16 peripheral clock disabled (default after reset)  
1: TIM16 peripheral clock enabled
- Bit 16 **TIM15EN**: TIM15 peripheral clock enable  
Set and reset by software.  
0: TIM15 peripheral clock disabled (default after reset)  
1: TIM15 peripheral clock enabled
- Bits 15:14 Reserved, must be kept at reset value.
- Bit 13 **SPI4EN**: SPI4 Peripheral Clocks Enable  
Set and reset by software.  
0: SPI4 peripheral clocks disabled (default after reset)  
1: SPI4 peripheral clocks enabled:  
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to **spi\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.
- Bit 12 **SPI1EN**: SPI1 Peripheral Clocks Enable  
Set and reset by software.  
0: SPI1 peripheral clocks disabled (default after reset)  
1: SPI1 peripheral clocks enabled:  
The peripheral clocks of the SPI1 are: the kernel clock selected by I2S123SRC and provided to **spi\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.
- Bits 11:6 Reserved, must be kept at reset value.
- Bit 5 **USART6EN**: USART6 Peripheral Clocks Enable  
Set and reset by software.  
0: USART6 peripheral clocks disabled (default after reset)  
1: USART6 peripheral clocks enabled:  
The peripheral clocks of the USART6 are: the kernel clock selected by USART16SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.

Bit 4 **USART1EN**: USART1 Peripheral Clocks Enable

Set and reset by software.

0: USART1 peripheral clocks disabled (default after reset)

1: USART1 peripheral clocks enabled:

The peripheral clocks of the USART1 are: the kernel clock selected by USART16SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8EN**: TIM8 peripheral clock enable

Set and reset by software.

0: TIM8 peripheral clock disabled (default after reset)

1: TIM8 peripheral clock enabled

Bit 0 **TIM1EN**: TIM1 peripheral clock enable

Set and reset by software.

0: TIM1 peripheral clock disabled (default after reset)

1: TIM1 peripheral clock enabled

### 8.7.46 RCC APB4 Clock Register (RCC\_APB4ENR)

This register can be accessed via two different offset address.

**Table 65. RCC\_APB4ENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB4ENR	0x0F4	0x0001 0000
RCC_C1_APB4ENR	0x154	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SAI4EN	Res.	Res.	Res.	Res.	RTCAPBEN
										rw					rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VREFEN	COMP12EN	Res.	LPTIM5EN	LPTIM4EN	LPTIM3EN	LPTIM2EN	Res.	I2C4EN	Res.	SPI6EN	Res.	LPUART1EN	Res.	SYSCFGEN	Res.
rw	rw		rw	rw	rw	rw		rw		rw		rw		rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **SAI4EN**: SAI4 Peripheral Clocks Enable

Set and reset by software.

0: SAI4 peripheral clocks disabled (default after reset)

1: SAI4 peripheral clocks enabled

The peripheral clocks of the SAI4 are: the kernel clocks selected by SAI4ASEL and SAI4BSEL, and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs respectively, and the **rcc\_pclk4** bus interface clock.

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBEN**: RTC APB Clock Enable

Set and reset by software.

0: The register clock interface of the RTC (APB) is disabled

1: The register clock interface of the RTC (APB) is enabled (default after reset)

Bit 15 **VREFEN**: VREF peripheral clock enable

Set and reset by software.

0: VREF peripheral clock disabled (default after reset)

1: VREF peripheral clock enabled

Bit 14 **COMP12EN**: COMP1/2 peripheral clock enable

Set and reset by software.

0: COMP1/2 peripheral clock disabled (default after reset)

1: COMP1/2 peripheral clock enabled

Bit 13 Reserved, must be kept at reset value.

- Bit 12 **LPTIM5EN**: LPTIM5 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM5 peripheral clocks disabled (default after reset)  
1: LPTIM5 peripheral clocks enabled  
The peripheral clocks of the LPTIM5 are: the kernel clock selected by LPTIM345SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 11 **LPTIM4EN**: LPTIM4 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM4 peripheral clocks disabled (default after reset)  
1: LPTIM4 peripheral clocks enabled  
The peripheral clocks of the LPTIM4 are: the kernel clock selected by LPTIM345SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 10 **LPTIM3EN**: LPTIM3 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM3 peripheral clocks disabled (default after reset)  
1: LPTIM3 peripheral clocks enabled  
The peripheral clocks of the LPTIM3 are: the kernel clock selected by LPTIM345SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 9 **LPTIM2EN**: LPTIM2 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM2 peripheral clocks disabled (default after reset)  
1: LPTIM2 peripheral clocks enabled  
The peripheral clocks of the LPTIM2 are: the kernel clock selected by LPTIM2SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 8 Reserved, must be kept at reset value.
- Bit 7 **I2C4EN**: I2C4 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C4 peripheral clocks disabled (default after reset)  
1: I2C4 peripheral clocks enabled  
The peripheral clocks of the I2C4 are: the kernel clock selected by I2C4SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 6 Reserved, must be kept at reset value.
- Bit 5 **SPI6EN**: SPI6 Peripheral Clocks Enable  
Set and reset by software.  
0: SPI6 peripheral clocks disabled (default after reset)  
1: SPI6 peripheral clocks enabled  
The peripheral clocks of the SPI6 are: the kernel clock selected by SPI6SEL and provided to **spi\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 4 Reserved, must be kept at reset value.
- Bit 3 **LPUART1EN**: LPUART1 Peripheral Clocks Enable  
Set and reset by software.  
0: LPUART1 peripheral clocks disabled (default after reset)  
1: LPUART1 peripheral clocks enabled  
The peripheral clocks of the LPUART1 are: the kernel clock selected by LPUART1SEL and provided to **lpuart\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGEN**: SYSCFG peripheral clock enable

Set and reset by software.

0: SYSCFG peripheral clock disabled (default after reset)

1: SYSCFG peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

### 8.7.47 RCC AHB3 Sleep Clock Register (RCC\_AHB3LPENR)

This register can be accessed via two different offset address.

**Table 66. RCC\_AHB3LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB3LPENR	0x0FC	0xF001 5131
RCC_C1_AHB3LPENR	0x15C	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AXISRAMLPEN	ITCMLPEN	DTCM2LPEN	DTCM1LPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDMMC1LPEN
r/w	r/w	r/w	r/w												r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	QSPILPEN	Res.	FMCLPEN	Res.	Res.	Res.	FLASHLPEN	Res.	Res.	JPGDECLPEN	DMA2DLPEN	Res.	Res.	Res.	MDMALPEN
	r/w		r/w				r/w			r/w	r/w				r/w

- Bit 31 **AXISRAMLPEN**: AXISRAM Block Clock Enable During CSleep mode  
Set and reset by software.  
0: AXISRAM interface clock disabled during CSleep mode  
1: AXISRAM interface clock enabled during CSleep mode (default after reset)
- Bit 30 **ITCMLPEN**: D1ITCM Block Clock Enable During CSleep mode  
Set and reset by software.  
0: D1 ITCM interface clock disabled during CSleep mode  
1: D1 ITCM interface clock enabled during CSleep mode (default after reset)
- Bit 29 **DTCM2LPEN**: D1 DTCM2 Block Clock Enable During CSleep mode  
Set and reset by software.  
0: D1 DTCM2 interface clock disabled during CSleep mode  
1: D1 DTCM2 interface clock enabled during CSleep mode (default after reset)
- Bit 28 **D1DTCM1LPEN**: D1DTCM1 Block Clock Enable During CSleep mode  
Set and reset by software.  
0: D1DTCM1 interface clock disabled during CSleep mode  
1: D1DTCM1 interface clock enabled during CSleep mode (default after reset)
- Bits 27:17 Reserved, must be kept at reset value.
- Bit 16 **SDMMC1LPEN**: SDMMC1 and SDMMC1 Delay Clock Enable During CSleep Mode  
Set and reset by software.  
0: SDMMC1 and SDMMC1 Delay clock disabled during CSleep mode  
1: SDMMC1 and SDMMC1 Delay clock enabled during CSleep mode (default after reset)
- Bit 15 Reserved, must be kept at reset value.

- Bit 14 **QSPILPEN**: QUADSPI and QUADSPI Delay Clock Enable During CSleep Mode  
Set and reset by software.  
0: QUADSPI and QUADSPI Delay clock disabled during CSleep mode  
1: QUADSPI and QUADSPI Delay clock enabled during CSleep mode (default after reset)
- Bit 13 Reserved, must be kept at reset value.
- Bit 12 **FMCLPEN**: FMC Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: FMC peripheral clocks disabled during CSleep mode  
1: FMC peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the FMC are: the kernel clock selected by FMCSEL and provided to **fmc\_ker\_ck** input, and the **rcc\_hclk3** bus interface clock.
- Bits 11:9 Reserved, must be kept at reset value.
- Bit 8 **FLASHLPEN**: Flash interface Clock Enable During CSleep Mode  
Set and reset by software.  
0: Flash interface clock disabled during CSleep mode  
1: Flash interface clock enabled during CSleep mode (default after reset)
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **JPGDECLPEN**: JPGDEC Clock Enable During CSleep Mode  
Set and reset by software.  
0: JPGDEC peripheral clock disabled during CSleep mode  
1: JPGDEC peripheral clock enabled during CSleep mode (default after reset)
- Bit 4 **DMA2DLPEN**: DMA2D Clock Enable During CSleep Mode  
Set and reset by software.  
0: DMA2D peripheral clock disabled during CSleep mode  
1: DMA2D peripheral clock enabled during CSleep mode (default after reset)
- Bits 3:1 Reserved, must be kept at reset value.
- Bit 0 **MDMALPEN**: MDMA Clock Enable During CSleep Mode  
Set and reset by software.  
0: MDMA peripheral clock disabled during CSleep mode  
1: MDMA peripheral clock enabled during CSleep mode (default after reset)

### 8.7.48 RCC AHB1 Sleep Clock Register (RCC\_AHB1LPENR)

This register can be accessed via two different offset address.

**Table 67. RCC\_AHB1LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB1LPENR	0x100	0x1E03 C023
RCC_C1_AHB1LPENR	0x160	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	USB2ULPILPEN	USB2OTGLPEN	USB1ULPILPEN	USB1OTGLPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ETH1RXLPEN	ETH1TXLPEN
			rw	rw	rw	rw								rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETH1MACLPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ADC12LPEN	Res.	Res.	Res.	DMA2LPEN	DMA1LPEN
rw										rw				rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **USB2ULPILPEN**: USB\_PHY2 clocks enable during CSleep mode

Set and reset by software.

0: USB\_PHY2 clocks disabled during CSleep mode

1: USB\_PHY2 clocks enabled during CSleep mode (default after reset)

Bit 27 **USB2OTGLPEN**: USB2OTG peripheral clock enable during CSleep mode

Set and reset by software.

0: USB2OTG peripheral clocks disabled during CSleep mode

1: USB2OTG peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the USB2OTG are: the kernel clock selected by USBSEL and the **rcc\_hclk1** bus interface clock.

Bit 26 **USB1ULPILPEN**: USB\_PHY1 clock enable during CSleep mode

Set and reset by software.

0: USB\_PHY1 peripheral clock disabled during CSleep mode

1: USB\_PHY1 peripheral clock enabled during CSleep mode (default after reset)

Bit 25 **USB1OTGLPEN**: USB1OTG peripheral clock enable during CSleep mode

Set and reset by software.

0: USB1OTG peripheral clock disabled during CSleep mode

1: USB1OTG peripheral clock enabled during CSleep mode (default after reset)

The peripheral clocks of the USB1OTG are: the kernel clock selected by USBSEL and the **rcc\_hclk1** bus interface clock.

Bits 24:18 Reserved, must be kept at reset value.

Bit 17 **ETH1RXLPEN**: Ethernet Reception Clock Enable During CSleep Mode

Set and reset by software.

0: Ethernet Reception clock disabled during CSleep mode

1: Ethernet Reception clock enabled during CSleep mode (default after reset)

Bit 16 **ETH1TXLPEN**: Ethernet Transmission Clock Enable During CSleep Mode

Set and reset by software.

0: Ethernet Transmission clock disabled during CSleep mode

1: Ethernet Transmission clock enabled during CSleep mode (default after reset)

Bit 15 **ETH1MACLPEN**: Ethernet MAC bus interface Clock Enable During CSleep Mode

Set and reset by software.

0: Ethernet MAC bus interface clock disabled during CSleep mode

1: Ethernet MAC bus interface clock enabled during CSleep mode (default after reset)

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12LPEN**: ADC1/2 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: ADC1/2 peripheral clocks disabled during CSleep mode

1: ADC1/2 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the ADC1&2 are: the kernel clock selected by ADCSEL and provided to `adc_ker_ck` input, and the `rcc_hclk1` bus interface clock.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2LPEN**: DMA2 Clock Enable During CSleep Mode

Set and reset by software.

0: DMA2 clock disabled during CSleep mode

1: DMA2 clock enabled during CSleep mode (default after reset)

Bit 0 **DMA1LPEN**: DMA1 Clock Enable During CSleep Mode

Set and reset by software.

0: DMA1 clock disabled during CSleep mode

1: DMA1 clock enabled during CSleep mode (default after reset)

### 8.7.49 RCC AHB2 Sleep Clock Register (RCC\_AHB2LPENR)

This register can be accessed via two different offset address.

**Table 68. RCC\_AHB2LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB2LPENR	0x104	0xE000 0271
RCC_C1_AHB2LPENR	0x164	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRAM3LPEN	SRAM2LPEN	SRAM1LPEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r/w	r/w	r/w													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- Bit 31 **SRAM3LPEN**: SRAM3 Clock Enable During CSleep Mode  
Set and reset by software.  
0: SRAM3 clock disabled during CSleep mode  
1: SRAM3 clock enabled during CSleep mode (default after reset)
- Bit 30 **SRAM2LPEN**: SRAM2 Clock Enable During CSleep Mode  
Set and reset by software.  
0: SRAM2 clock disabled during CSleep mode  
1: SRAM2 clock enabled during CSleep mode (default after reset)
- Bit 29 **SRAM1LPEN**: SRAM1 Clock Enable During CSleep Mode  
Set and reset by software.  
0: SRAM1 clock disabled during CSleep mode  
1: SRAM1 clock enabled during CSleep mode (default after reset)

Bits 28:10 Reserved, must be kept at reset value.

- Bit 9 **SDMMC2LPEN**: SDMMC2 and SDMMC2 Delay Clock Enable During CSleep Mode  
Set and reset by software.  
0: SDMMC2 and SDMMC2 Delay clock disabled during CSleep mode  
1: SDMMC2 and SDMMC2 Delay clock enabled during CSleep mode (default after reset)

Bits 8:7 Reserved, must be kept at reset value.

- Bit 6 **RNGLPEN**: RNG peripheral clock enable during CSleep mode  
Set and reset by software.  
0: RNG peripheral clocks disabled during CSleep mode  
1: RNG peripheral clock enabled during CSleep mode (default after reset)  
The peripheral clocks of the RNG are: the kernel clock selected by RNGSEL and provided to **rng\_ker\_ck** input, and the **rcc\_hclk2** bus interface clock.

Bit 5 **HASHLPEN**: HASH peripheral clock enable during CSleep mode

Set and reset by software.

0: HASH peripheral clock disabled during CSleep mode

1: HASH peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **CRYPTLPEN**: CRYPT peripheral clock enable during CSleep mode

Set and reset by software.

0: CRYPT peripheral clock disabled during CSleep mode

1: CRYPT peripheral clock enabled during CSleep mode (default after reset)

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMILPEN**: DCMI peripheral clock enable during CSleep mode

Set and reset by software.

0: DCMI peripheral clock disabled during CSleep mode

1: DCMI peripheral clock enabled during CSleep mode (default after reset)

### 8.7.50 RCC AHB4 Sleep Clock Register (RCC\_AHB4LPENR)

This register can be accessed via two different offset address.

**Table 69. RCC\_AHB4LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_AHB4LPENR	0x108	0x3128 07FF
RCC_C1_AHB4LPENR	0x168	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SRAM4LPEN	BKPRAMLLEN	Res.	Res.	Res.	ADC3LPEN	Res.	Res.	BDMALLEN	Res.	CRCLLEN	Res.	Res.	Res.
		rw	rw				rw			rw		rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	GPIOKLEN	GPIOJLEN	GPIOILEN	GPIOHLEN	GPIOGLLEN	GPIOFLEN	GPIOELLEN	GPIODLEN	GPIOCLLEN	GPIOBLLEN	GPIOALEN
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

**Bit 29 SRAM4LPEN:** SRAM4 Clock Enable During CSleep Mode

Set and reset by software.

0: SRAM4 clock disabled during CSleep mode

1: SRAM4 clock enabled during CSleep mode (default after reset)

**Bit 28 BKPRAMLLEN:** Backup RAM Clock Enable During CSleep Mode

Set and reset by software.

0: Backup RAM clock disabled during CSleep mode

1: Backup RAM clock enabled during CSleep mode (default after reset)

Bits 27:25 Reserved, must be kept at reset value.

**Bit 24 ADC3LPEN:** ADC3 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: ADC3 peripheral clocks disabled during CSleep mode

1: ADC3 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the ADC3 are: the kernel clock selected by ADCSEL and provided to adc\_ker\_ck input, and the **rcc\_hclk4** bus interface clock.

Bits 23:22 Reserved, must be kept at reset value.

**Bit 21 BDMALLEN:** BDMA Clock Enable During CSleep Mode

Set and reset by software.

0: BDMA clock disabled during CSleep mode

1: BDMA clock enabled during CSleep mode (default after reset)

**Bit 20** Reserved, must be kept at reset value.

Bit 19 **CRCLPEN**: CRC peripheral clock enable during CSleep mode  
Set and reset by software.  
0: CRC peripheral clock disabled during CSleep mode  
1: CRC peripheral clock enabled during CSleep mode (default after reset)

Bits 18:11 Reserved, must be kept at reset value.

Bit 10 **GPIOKLPEN**: GPIOK peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOK peripheral clock disabled during CSleep mode  
1: GPIOK peripheral clock enabled during CSleep mode (default after reset)

Bit 9 **GPIOJLPEN**: GPIOJ peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOJ peripheral clock disabled during CSleep mode  
1: GPIOJ peripheral clock enabled during CSleep mode (default after reset)

Bit 8 **GPIOILPEN**: GPIOI peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOI peripheral clock disabled during CSleep mode  
1: GPIOI peripheral clock enabled during CSleep mode (default after reset)

Bit 7 **GPIOHLPEN**: GPIOH peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOH peripheral clock disabled during CSleep mode  
1: GPIOH peripheral clock enabled during CSleep mode (default after reset)

Bit 6 **GPIOGLPEN**: GPIOG peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOG peripheral clock disabled during CSleep mode  
1: GPIOG peripheral clock enabled during CSleep mode (default after reset)

Bit 5 **GPIOFLPEN**: GPIOF peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOF peripheral clock disabled during CSleep mode  
1: GPIOF peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **GPIOELPEN**: GPIOE peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOE peripheral clock disabled during CSleep mode  
1: GPIOE peripheral clock enabled during CSleep mode (default after reset)

Bit 3 **GPIODLPEN**: GPIOD peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOD peripheral clock disabled during CSleep mode  
1: GPIOD peripheral clock enabled during CSleep mode (default after reset)

- Bit 2 **GPIOCLPEN**: GPIOC peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOC peripheral clock disabled during CSleep mode  
1: GPIOC peripheral clock enabled during CSleep mode (default after reset)
- Bit 1 **GPIOBLPEN**: GPIOB peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOB peripheral clock disabled during CSleep mode  
1: GPIOB peripheral clock enabled during CSleep mode (default after reset)
- Bit 0 **GPIOALPEN**: GPIOA peripheral clock enable during CSleep mode  
Set and reset by software.  
0: GPIOA peripheral clock disabled during CSleep mode  
1: GPIOA peripheral clock enabled during CSleep mode (default after reset)

### 8.7.51 RCC APB3 Sleep Clock Register (RCC\_APB3LPENR)

This register can be accessed via two different offset address.

**Table 70. RCC\_APB3LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB3LPENR	0x10C	0x0000 0058
RCC_C1_APB3LPENR	0x16C	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WWDG1LPEN	Res.	Res.	LTDCLPEN	Res.	Res.	Res.
									rw			rw			

Bits 31:5 Reserved, must be kept at reset value.

Bit 6 **WWDG1LPEN**: WWDG1 Clock Enable During CSleep Mode

Set and reset by software.

0: WWDG1 clock disable during CSleep mode

1: WWDG1 clock enabled during CSleep mode (default after reset)

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **LTDCLPEN**: LTDC peripheral clock enable during CSleep mode

Provides the pixel clock (**ltdc\_ker\_ck**) to the LTDC block.

Set and reset by software.

0: LTDC clock disabled during CSleep mode

1: LTDC clock provided to the LTDC during CSleep mode (default after reset)

Bits 2:0 Reserved, must be kept at reset value.

### 8.7.52 RCC APB1 Low Sleep Clock Register (RCC\_APB1LLPENR)

This register can be accessed via two different offset address.

**Table 71. RCC\_APB1LLPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB1LLPENR	0x110	0xE8FF CBFF
RCC_C1_APB1LLPENR	0x170	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
USART8LPEN	USART7LPEN	DAC12LPEN	Res.	CECLPEN	Res.	Res.	Res.	I2C3LPEN	I2C2LPEN	I2C1LPEN	UART5LPEN	UART4LPEN	USART3LPEN	USART2LPEN	SPDIFRXLPEN
r/w	r/w	r/w		r/w				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SPI3LPEN	SPI2LPEN	Res.	Res.	Res.	Res.	LPTIM1LPEN	TIM14LPEN	TIM13LPEN	TIM12LPEN	TIM7LPEN	TIM6LPEN	TIM5LPEN	TIM4LPEN	TIM3LPEN	TIM2LPEN
r/w	r/w					r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

- Bit 31 USART8LPEN:** USART8 Peripheral Clocks Enable During CSleep Mode  
 Set and reset by software.  
 0: USART8 peripheral clocks disabled during CSleep mode  
 1: USART8 peripheral clocks enabled during CSleep mode (default after reset):  
 The peripheral clocks of the USART8 are: the kernel clock selected by USART234578SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 30 USART7LPEN:** USART7 Peripheral Clocks Enable During CSleep Mode  
 Set and reset by software.  
 0: USART7 peripheral clocks disabled during CSleep mode  
 1: USART7 peripheral clocks enabled during CSleep mode (default after reset):  
 The peripheral clocks of the USART7 are: the kernel clock selected by USART234578SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 29 DAC12LPEN:** DAC1/2 peripheral clock enable during CSleep mode  
 Set and reset by software.  
 0: DAC1/2 peripheral clock disabled during CSleep mode  
 1: DAC1/2 peripheral clock enabled during CSleep mode (default after reset)
- Bit 28** Reserved, must be kept at reset value.
- Bit 27 CECLPEN:** HDMI-CEC Peripheral Clocks Enable During CSleep Mode  
 Set and reset by software.  
 0: HDMI-CEC peripheral clocks disabled during CSleep mode  
 1: HDMI-CEC peripheral clocks enabled during CSleep mode (default after reset)  
 The peripheral clocks of the HDMI-CEC are: the kernel clock selected by CECSEL and provided to **cec\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bits 26:24** Reserved, must be kept at reset value.

- Bit 23 **I2C3LPEN**: I2C3 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C3 peripheral clocks disabled during CSleep mode  
1: I2C3 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the I2C3 are: the kernel clock selected by I2C123SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 22 **I2C2LPEN**: I2C2 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C2 peripheral clocks disabled during CSleep mode  
1: I2C2 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the I2C2 are: the kernel clock selected by I2C123SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 21 **I2C1LPEN**: I2C1 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C1 peripheral clocks disabled during CSleep mode  
1: I2C1 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the I2C1 are: the kernel clock selected by I2C123SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 20 **UART5LPEN**: UART5 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: UART5 peripheral clocks disabled during CSleep mode  
1: UART5 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the UART5 are: the kernel clock selected by USART234578SEL and provided to **uart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 19 **UART4LPEN**: UART4 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: UART4 peripheral clocks disabled during CSleep mode  
1: UART4 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the UART4 are: the kernel clock selected by USART234578SEL and provided to **uart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 18 **USART3LPEN**: USART3 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: USART3 peripheral clocks disabled during CSleep mode  
1: USART3 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the USART3 are: the kernel clock selected by USART234578SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 17 **USART2LPEN**: USART2 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: USART2 peripheral clocks disabled during CSleep mode  
1: USART2 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the USART2 are: the kernel clock selected by USART234578SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.
- Bit 16 **SPDIFRXLPEN**: SPDIFRX Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SPDIFRX peripheral clocks disabled during CSleep mode  
1: SPDIFRX peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SPDIFRX are: the kernel clock selected by SPDIFSEL and provided to **spdifrx\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 15 **SPI3LPEN**: SPI3 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SPI3 peripheral clocks disabled during CSleep mode

1: SPI3 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SPI3 are: the kernel clock selected by I2S123SRC and provided to **spi\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 14 **SPI2LPEN**: SPI2 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SPI2 peripheral clocks disabled during CSleep mode

1: SPI2 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SPI2 are: the kernel clock selected by I2S123SRC and provided to **spi\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: LPTIM1 peripheral clocks disabled during CSleep mode

1: LPTIM1 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the LPTIM1 are: the kernel clock selected by LPTIM1SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 8 **TIM14LPEN**: TIM14 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM14 peripheral clock disabled during CSleep mode

1: TIM14 peripheral clock enabled during CSleep mode (default after reset)

Bit 7 **TIM13LPEN**: TIM13 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM13 peripheral clock disabled during CSleep mode

1: TIM13 peripheral clock enabled during CSleep mode (default after reset)

Bit 6 **TIM12LPEN**: TIM12 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM12 peripheral clock disabled during CSleep mode

1: TIM12 peripheral clock enabled during CSleep mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM7 peripheral clock disabled during CSleep mode

1: TIM7 peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM6 peripheral clock disabled during CSleep mode

1: TIM6 peripheral clock enabled during CSleep mode (default after reset)

Bit 3 **TIM5LPEN**: TIM5 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM5 peripheral clock disabled during CSleep mode

1: TIM5 peripheral clock enabled during CSleep mode (default after reset)

- Bit 2 **TIM4LPEN**: TIM4 peripheral clock enable during CSleep mode  
Set and reset by software.  
0: TIM4 peripheral clock disabled during CSleep mode  
1: TIM4 peripheral clock enabled during CSleep mode (default after reset)
- Bit 1 **TIM3LPEN**: TIM3 peripheral clock enable during CSleep mode  
Set and reset by software.  
0: TIM3 peripheral clock disabled during CSleep mode  
1: TIM3 peripheral clock enabled during CSleep mode (default after reset)
- Bit 0 **TIM2LPEN**: TIM2 peripheral clock enable during CSleep mode  
Set and reset by software.  
0: TIM2 peripheral clock disabled during CSleep mode  
1: TIM2 peripheral clock enabled during CSleep mode (default after reset)

### 8.7.53 RCC APB1 High Sleep Clock Register (RCC\_APB1HLPENR)

This register can be accessed via two different offset address.

**Table 72. RCC\_APB1HLPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB1HLPENR	0x114	0x0000 0136
RCC_C1_APB1HLPENR	0x174	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FDCANLPEN	Res.	Res.	MDIOSLPEN	OPAMPLPEN	Res.	SWPLPEN	CRSLPEN	Res.
							RW			RW	RW		RW	RW	

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **FDCANLPEN**: FDCAN Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: FDCAN peripheral clocks disabled during CSleep mode

1: FDCAN peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the FDCAN are: the kernel clock selected by FDCANSEL and provided to **fdcan\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSLPEN**: MDIOS peripheral clock enable during CSleep mode

Set and reset by software.

0: MDIOS peripheral clock disabled during CSleep mode

1: MDIOS peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **OPAMPLPEN**: OPAMP peripheral clock enable during CSleep mode

Set and reset by software.

0: OPAMP peripheral clock disabled during CSleep mode

1: OPAMP peripheral clock enabled during CSleep mode (default after reset)

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SWPLPEN**: SWPMI Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SWPMI peripheral clocks disabled during CSleep mode

1: SWPMI peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SWPMI are: the kernel clock selected by SWPSEL and provided to **swpmi\_ker\_ck** input, and the **rcc\_pclk1** bus interface clock.

Bit 1 **CRSLPEN**: Clock Recovery System peripheral clock enable during CSleep mode

Set and reset by software.

0: CRS peripheral clock disabled during CSleep mode

1: CRS peripheral clock enabled during CSleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

### 8.7.54 RCC APB2 Sleep Clock Register (RCC\_APB2LPENR)

This register can be accessed via two different offset address.

**Table 73. RCC\_APB2LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB2LPENR	0x118	0x31D7 3033
RCC_C1_APB2LPENR	0x178	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	HRTIMLPEN	DFSDM1LPEN	Res.	Res.	Res.	SAI3LPEN	SAI2LPEN	SAI1LPEN	Res.	SPI5LPEN	Res.	TIM17LPEN	TIM16LPEN	TIM15LPEN
		rw	rw				rw	rw	rw		rw		rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	SPI4LPEN	SPI1LPEN	Res.	Res.	Res.	Res.	Res.	Res.	USART6LPEN	USART1LPEN	Res.	Res.	TIM8LPEN	TIM1LPEN
		rw	rw							rw	rw			rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **HRTIMLPEN**: HRTIM peripheral clock enable during CSleep mode

Set and reset by software.

0: HRTIM peripheral clock disabled during CSleep mode

1: HRTIM peripheral clock enabled during CSleep mode (default after reset)

Bit 28 **DFSDM1LPEN**: DFSDM1 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: DFSDM1 peripheral clocks disabled during CSleep mode

1: DFSDM1 peripheral clocks enabled during CSleep mode (default after reset)

DFSDM1 peripheral clocks are: the kernel clocks selected by SAI1SEL and DFSDM1SEL and provided to **Aclk** and **clk** inputs respectively, and the **rcc\_pclk2** bus interface clock.

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **SAI3LPEN**: SAI3 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SAI3 peripheral clocks disabled during CSleep mode

1: SAI3 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SAI3 are: the kernel clock selected by SAI23SEL and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.

Bit 23 **SAI2LPEN**: SAI2 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SAI2 peripheral clocks disabled during CSleep mode

1: SAI2 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SAI2 are: the kernel clock selected by SAI23SEL and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.

- Bit 22 **SAI1LPEN**: SAI1 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SAI1 peripheral clocks disabled during CSleep mode  
1: SAI1 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.
- Bit 21 Reserved, must be kept at reset value.
- Bit 20 **SPI5LPEN**: SPI5 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SPI5 peripheral clocks disabled during CSleep mode  
1: SPI5 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SPI5 are: the kernel clock selected by SPI45SEL and provided to **spi\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.
- Bit 19 Reserved, must be kept at reset value.
- Bit 18 **TIM17LPEN**: TIM17 peripheral clock enable during CSleep mode  
Set and reset by software.  
0: TIM17 peripheral clock disabled during CSleep mode  
1: TIM17 peripheral clock enabled during CSleep mode (default after reset)
- Bit 17 **TIM16LPEN**: TIM16 peripheral clock enable during CSleep mode  
Set and reset by software.  
0: TIM16 peripheral clock disabled during CSleep mode  
1: TIM16 peripheral clock enabled during CSleep mode (default after reset)
- Bit 16 **TIM15LPEN**: TIM15 peripheral clock enable during CSleep mode  
Set and reset by software.  
0: TIM15 peripheral clock disabled during CSleep mode  
1: TIM15 peripheral clock enabled during CSleep mode (default after reset)
- Bits 15:14 Reserved, must be kept at reset value.
- Bit 13 **SPI4LPEN**: SPI4 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SPI4 peripheral clocks disabled during CSleep mode  
1: SPI4 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to **spi\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.
- Bit 12 **SPI1LPEN**: SPI1 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SPI1 peripheral clocks disabled during CSleep mode  
1: SPI1 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SPI1 are: the kernel clock selected by I2S123SRC and provided to **spi\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.
- Bits 11:6 Reserved, must be kept at reset value.
- Bit 5 **USART6LPEN**: USART6 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: USART6 peripheral clocks disabled during CSleep mode  
1: USART6 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the USART6 are: the kernel clock selected by USART16SEL and provided to **usart\_ker\_ck** input, and the **rcc\_pclk2** bus interface clock.

Bit 4 **USART1LPEN**: USART1 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: USART1 peripheral clocks disabled during CSleep mode

1: USART1 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the USART1 are: the kernel clock selected by USART16SEL and provided to **usart\_ker\_ck** inputs, and the **rcc\_pclk2** bus interface clock.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPEN**: TIM8 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM8 peripheral clock disabled during CSleep mode

1: TIM8 peripheral clock enabled during CSleep mode (default after reset)

Bit 0 **TIM1LPEN**: TIM1 peripheral clock enable during CSleep mode

Set and reset by software.

0: TIM1 peripheral clock disabled during CSleep mode

1: TIM1 peripheral clock enabled during CSleep mode (default after reset)

### 8.7.55 RCC APB4 Sleep Clock Register (RCC\_APB4LPENR)

This register can be accessed via two different offset address.

**Table 74. RCC\_APB4LPENR address offset and reset value**

Register Name	Address Offset	Reset Value
RCC_APB4LPENR	0x11C	0x0421 DEAA
RCC_C1_APB4LPENR	0x17C	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SAI4LPEN	Res.	Res.	Res.	Res.	RTCAPBLPEN
										rw					rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VREFLPEN	COMP12LPEN	Res.	LPTIM5LPEN	LPTIM4LPEN	LPTIM3LPEN	LPTIM2LPEN	Res.	I2C4LPEN	Res.	SPI6LPEN	Res.	LPUART1LPEN	Res.	SYSCFGLPEN	Res.
rw	rw		rw	rw	rw	rw		rw		rw		rw		rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **SAI4LPEN**: SAI4 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SAI4 peripheral clocks disabled during CSleep mode

1: SAI4 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SAI4 are: the kernel clocks selected by SAI4ASEL and SAI4BSEL, and provided to **sai\_a\_ker\_ck** and **sai\_b\_ker\_ck** inputs respectively, and the **rcc\_pclk4** bus interface clock.

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBLPEN**: RTC APB Clock Enable During CSleep Mode

Set and reset by software.

0: The register clock interface of the RTC (APB) is disabled during CSleep mode

1: The register clock interface of the RTC (APB) is enabled during CSleep mode (default after reset)

Bit 15 **VREFLPEN**: VREF peripheral clock enable during CSleep mode

Set and reset by software.

0: VREF peripheral clock disabled during CSleep mode

1: VREF peripheral clock enabled during CSleep mode (default after reset)

Bit 14 **COMP12LPEN**: COMP1/2 peripheral clock enable during CSleep mode

Set and reset by software.

0: COMP1/2 peripheral clock disabled during CSleep mode

1: COMP1/2 peripheral clock enabled during CSleep mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

- Bit 12 **LPTIM5LPEN**: LPTIM5 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: LPTIM5 peripheral clocks disabled during CSleep mode  
1: LPTIM5 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the LPTIM5 are: the kernel clock selected by LPTIM345SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 11 **LPTIM4LPEN**: LPTIM4 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: LPTIM4 peripheral clocks disabled during CSleep mode  
1: LPTIM4 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the LPTIM4 are: the kernel clock selected by LPTIM345SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 10 **LPTIM3LPEN**: LPTIM3 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: LPTIM3 peripheral clocks disabled during CSleep mode  
1: LPTIM3 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the LPTIM3 are: the kernel clock selected by LPTIM345SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 9 **LPTIM2LPEN**: LPTIM2 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: LPTIM2 peripheral clocks disabled during CSleep mode  
1: LPTIM2 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the LPTIM5 are: the kernel clock selected by LPTIM2SEL and provided to **lptim\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 8 Reserved, must be kept at reset value.
- Bit 7 **I2C4LPEN**: I2C4 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C4 peripheral clocks disabled during CSleep mode  
1: I2C4 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the I2C4 are: the kernel clock selected by I2C4SEL and provided to **i2c\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 6 Reserved, must be kept at reset value.
- Bit 5 **SPI6LPEN**: SPI6 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SPI6 peripheral clocks disabled during CSleep mode  
1: SPI6 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SPI6 are: the kernel clock selected by SPI6SEL and provided to **spi\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.
- Bit 4 Reserved, must be kept at reset value.
- Bit 3 **LPUART1LPEN**: LPUART1 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: LPUART1 peripheral clocks disabled during CSleep mode  
1: LPUART1 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the LPUART1 are: the kernel clock selected by LPUART1SEL and provided to **lpuart\_ker\_ck** input, and the **rcc\_pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SYSCFGLPEN**: SYSCFG peripheral clock enable during CSleep mode  
Set and reset by software.

0: SYSCFG peripheral clock disabled during CSleep mode

1: SYSCFG peripheral clock enabled during CSleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

## 9 Clock recovery system (CRS)

### 9.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides a powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at precise 1-ms intervals.

The synchronization signal can also be derived from the LSE oscillator output or it can be generated by user software.

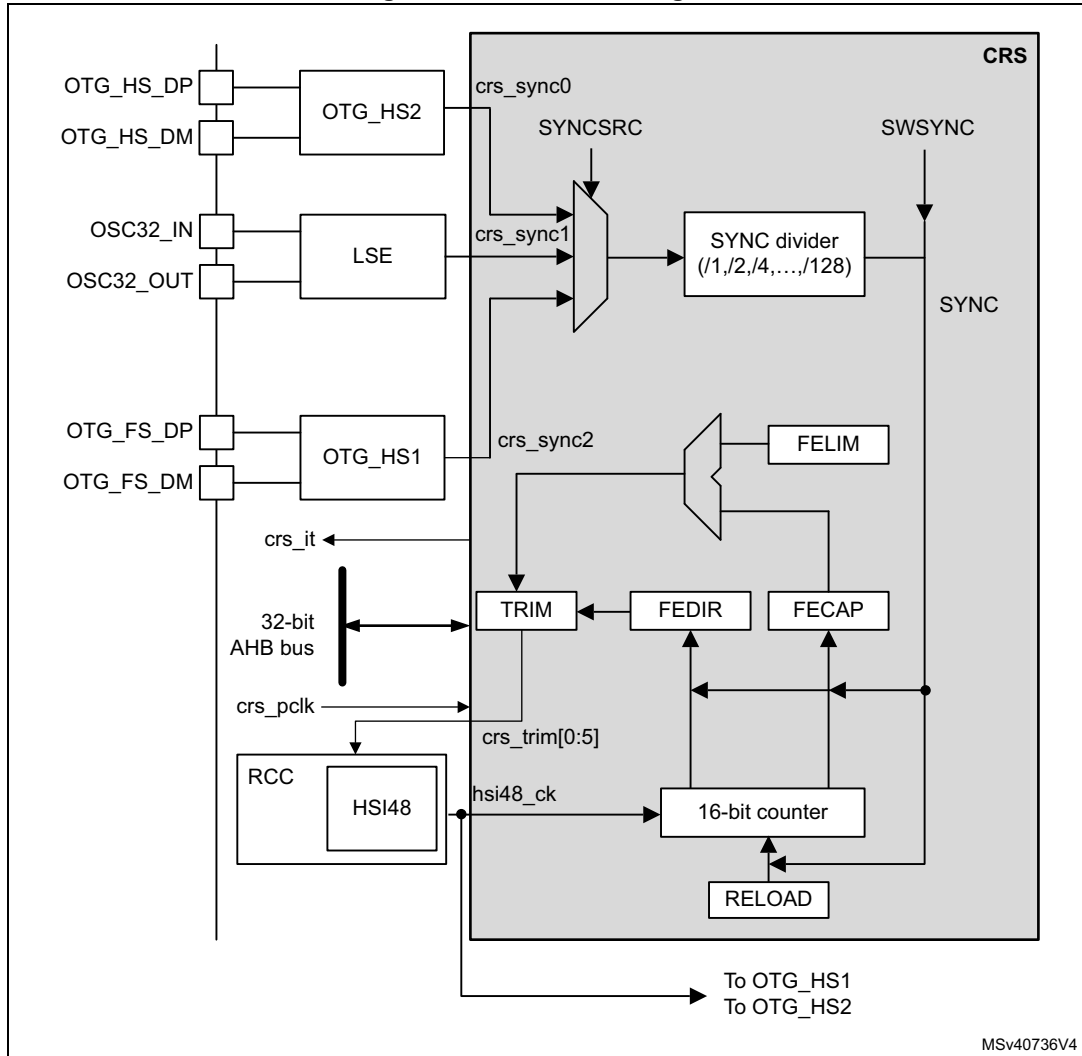

### 9.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - USB2 SOF packet reception
  - LSE oscillator output
  - USB1 SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

### 9.3 CRS functional description

#### 9.3.1 CRS block diagram

Figure 56. CRS block diagram

MSv40736V4

## 9.4 CRS internal signals

[Table 76](#) gives the list of CRS internal signals.

**Table 76. CRS internal input/output signals**

Signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
hsi48_ck	Digital input	HSI48 oscillator clock
crs_trim[0:5]	Digital output	HSI48 oscillator smooth trimming value
crs_sync0, crs_sync1, crs_sync2	Digital input	SYNC signal source selection (USB2, LSE, or USB1)

### 9.4.1 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS\_CFGR register, can be the signal from the LSE clock, the USB1 SOF signal, or the USB2 SOF signal. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to [Section 9.7.2: CRS configuration register \(CRS\\_CFGR\)](#).

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS\_CR register.

### 9.4.2 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS\_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS\_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value should be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value should be decremented).

Figure 57. CRS counter behavior

### 9.4.3 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS\_CFGR register
- WARNING LIMIT, defined as 3 \* FELIM value
- OUTRANGE (error limit), defined as 128 \* FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS\_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one and that then, no trimming action is necessary.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value will not be reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

*Note:* If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

*In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS\_CR register), the TRIM field of CRS\_CR is adjusted by hardware and is read-only.*

### 9.4.4 CRS initialization and configuration

#### RELOAD value

The RELOAD value should be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one in order to reach the expected synchronization on the zero value. The formula is the following:

$$\text{RELOAD} = (f_{\text{TARGET}} / f_{\text{SYNC}}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

**FELIM value**

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result should be always rounded up to the nearest integer value in order to obtain the best trimming response. If frequent trimming actions are not wanted in the application, the trimming hysteresis can be increased by increasing slightly the FELIM value.

The reset value of the FELIM field corresponds to  $(f_{TARGET} / f_{SYNC}) = 48000$  and to a typical trimming step size of 0.14%.

**Caution:** There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than  $128 * FELIM$  value (OUTRANGE limit).

**9.5 CRS low-power modes**

**Table 77. Effect of low-power modes on CRS**

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen.
Standby	The CRS stops operating until the Stop or Standby mode is exited and the HSI48 oscillator restarted.

**9.6 CRS interrupts**

**Table 78. Interrupt control bits**

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

## 9.7 CRS registers

Refer to [Section 1.1 on page 98](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

### 9.7.1 CRS control register (CRS\_CR)

Address offset: 0x00

Reset value: 0x0000 2000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TRIM[5:0]						SWSY NC	AUTOT RIMEN	CEN	Res.	ESYNC IE	ERRIE	SYNC WARNI E	SYNCO KIE
		rw	rw	rw	rw	rw	rw	rt_w	rw	rw		rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI48.

The default value is 32, which corresponds to the middle of the trimming interval. The trimming step is around 67 kHz between two consecutive TRIM steps. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to [Section 9.4.3: Frequency error evaluation and automatic trimming](#) for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS\_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

- Bit 3 **ESYNCIE**: Expected SYNC interrupt enable
  - 0: Expected SYNC (ESYNCF) interrupt disabled
  - 1: Expected SYNC (ESYNCF) interrupt enabled
- Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable
  - 0: Synchronization or trimming error (ERRF) interrupt disabled
  - 1: Synchronization or trimming error (ERRF) interrupt enabled
- Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable
  - 0: SYNC warning (SYNCWARNF) interrupt disabled
  - 1: SYNC warning (SYNCWARNF) interrupt enabled
- Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable
  - 0: SYNC event OK (SYNCOKF) interrupt disabled
  - 1: SYNC event OK (SYNCOKF) interrupt enabled

### 9.7.2 CRS configuration register (CRS\_CFGR)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS\_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

- Bit 31 **SYNCPOL**: SYNC polarity selection
  - This bit is set and cleared by software to select the input polarity for the SYNC signal source.
  - 0: SYNC active on rising edge (default)
  - 1: SYNC active on falling edge
- Bit 30 Reserved, must be kept at reset value.
- Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection
  - These bits are set and cleared by software to select the SYNC signal source.
  - 00: USB2 SOF selected as SYNC signal source
  - 01: LSE selected as SYNC signal source
  - 10: USB1 SOF selected as SYNC signal source (default)
  - 11: Reserved

*Note: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF will not be generated by the host. No SYNC signal will therefore be provided to the CRS to calibrate the HSI48 on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE should be used as SYNC signal.*
- Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

- These bits are set and cleared by software to control the division factor of the SYNC signal.
- 000: SYNC not divided (default)
- 001: SYNC divided by 2
- 010: SYNC divided by 4
- 011: SYNC divided by 8
- 100: SYNC divided by 16
- 101: SYNC divided by 32
- 110: SYNC divided by 64
- 111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS\_ISR register. Refer to [Section 9.4.3: Frequency error evaluation and automatic trimming](#) for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to [Section 9.4.2: Frequency error measurement](#) for more details about counter behavior.

### 9.7.3 CRS interrupt and status register (CRS\_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIMOVF	SYNCMISS	SYNCERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNCWARNF	SYNCOKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to [Section 9.4.3: Frequency error evaluation and automatic trimming](#) for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.  
 0: Upcounting direction, the actual frequency is above the target.  
 1: Downcounting direction, the actual frequency is below the target.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS\_CR register. It is cleared by software by setting the ERRC bit in the CRS\_ICR register.  
 0: No trimming error signaled  
 1: Trimming error signaled

**Bit 9 SYNCMISS:** SYNC missed

This flag is set by hardware when the frequency error counter reached value  $FELIM * 128$  and no SYNC was detected, meaning either that a SYNC pulse was missed or that the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, and that some other action should be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is set in the CRS\_CR register. It is cleared by software by setting the ERRC bit in the CRS\_ICR register.

0: No SYNC missed error signalized

1: SYNC missed error signalized

**Bit 8 SYNCERR:** SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to  $FELIM * 128$ . This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action should be taken. An interrupt is generated if the ERRIE bit is set in the CRS\_CR register. It is cleared by software by setting the ERRC bit in the CRS\_ICR register.

0: No SYNC error signalized

1: SYNC error signalized

Bits 7:4 Reserved, must be kept at reset value.

**Bit 3 ESYNCF:** Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCF bit is set in the CRS\_CR register. It is cleared by software by setting the ESYNCC bit in the CRS\_ICR register.

0: No expected SYNC signalized

1: Expected SYNC signalized

**Bit 2 ERRF:** Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS\_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS\_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signalized

1: Synchronization or trimming error signalized

**Bit 1 SYNCWARNF:** SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to  $FELIM * 3$ , but smaller than  $FELIM * 128$ . This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS\_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS\_ICR register.

0: No SYNC warning signalized

1: SYNC warning signalized

**Bit 0 SYNCOKF:** SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than  $FELIM * 3$ . This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS\_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS\_ICR register.

0: No SYNC event OK signalized

1: SYNC event OK signalized

### 9.7.4 CRS interrupt flag clear register (CRS\_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNCWARNC	SYNCOKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value

Bit 3 **ESYNCC**: Expected SYNC clear flag

Writing 1 to this bit clears the ESYNCF flag in the CRS\_ISR register.

Bit 2 **ERRC**: Error clear flag

Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS\_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag

Writing 1 to this bit clears the SYNCWARNF flag in the CRS\_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag

Writing 1 to this bit clears the SYNCOKF flag in the CRS\_ISR register.

9.7.5 CRS register map

Table 79. CRS register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 10 Hardware semaphore (HSEM)

### 10.1 Hardware semaphore introduction

The hardware semaphore block provides 32 (32-bit) register based semaphores.

The semaphores can be used to ensure synchronization between different processes running between different Cores. The HSEM provides a non blocking mechanism to lock semaphores in an atomic way. The following functions are provided:

- Locking a semaphore can be done in two ways:
  - 2-step lock: by writing CoreID and ProcessID to the semaphore, followed by a Read check
  - 1-step lock: by reading the CoreID from the semaphore
- Interrupt generation when a semaphore is freed
  - Each semaphore may generate an interrupt on one of the interrupt lines
- Semaphore clear protection
  - A semaphore will only be cleared when CoreID and ProcessID match
- Global semaphore clear per CoreID

### 10.2 Hardware semaphore main features

The HSEM includes the following features:

- 32 (32-bit) semaphores
- 8-bit ProcessID
- 4-bit CoreID
- 2 interrupt lines
- Lock indication

### 10.3 HSEM functional description

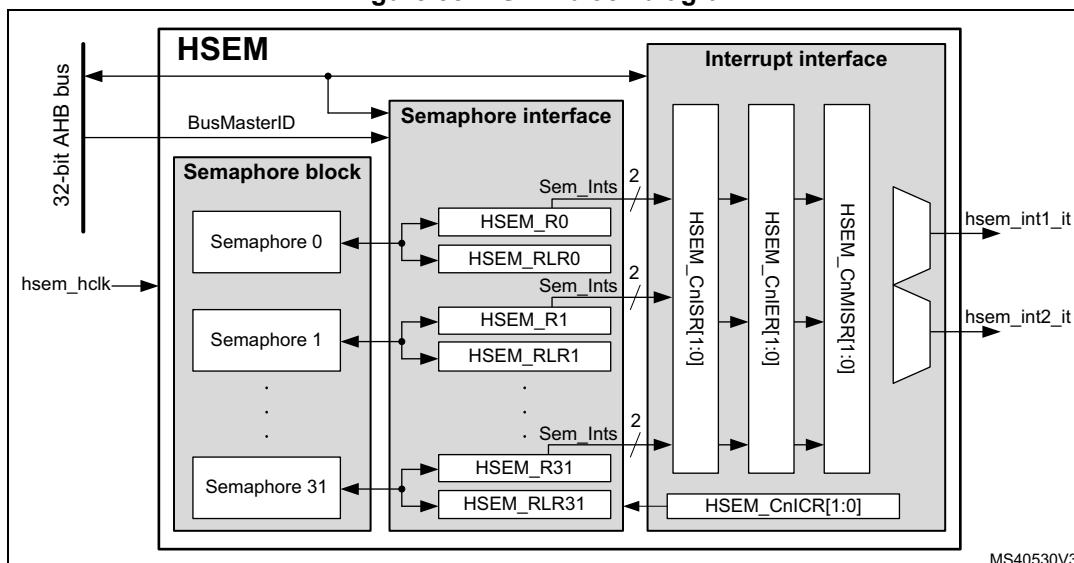

#### 10.3.1 HSEM block diagram

As shown in [Figure 58](#), the HSEM is based on three sub-blocks:

- The Semaphore block containing the semaphore status and IDs
- The Semaphore Interface block providing AHB access to the Semaphore via the HSEM\_R and HSEM\_RLR registers
- The Interrupt interface block providing control for the interrupts via the HSEM\_CnISR, HSEM\_CnIER, HSEM\_CnMISR, and HSEM\_CnICR registers

Figure 58. HSEM block diagram

### 10.3.2 HSEM internal signals

Table 80. HSEM internal input/output signals

Signal name	Signal type	Description
hsem_hclk	Digital input	AHB clock
hsem_int1_it	Digital output	Interrupt 1 line
hsem_int2_it	Digital output	Interrupt 2 line

### 10.3.3 HSEM lock procedures

There are two lock procedures:

- 2-step (Write) lock
- 1-step (Read) lock

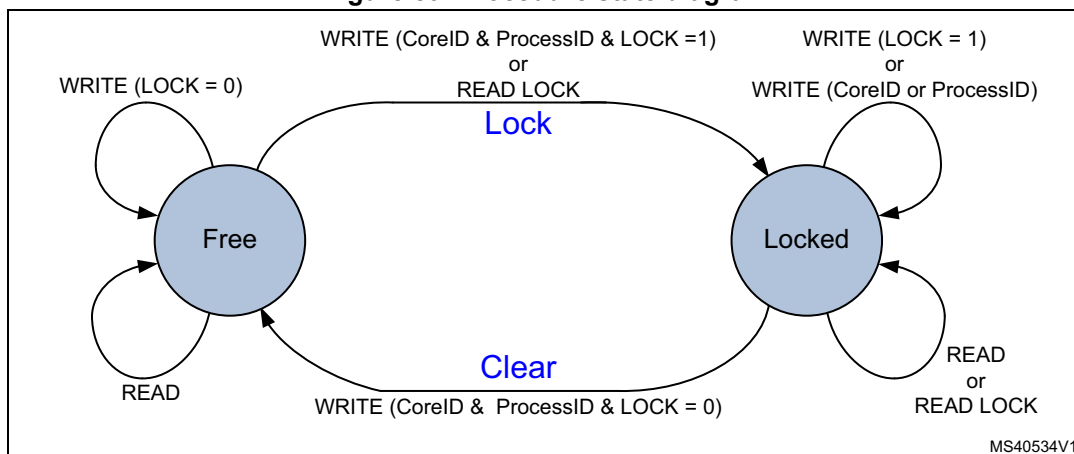

The semaphore is free when its lock bit is '0', in this case the CoreID and ProcessID are also '0'. When the lock bit is '1' the semaphore is locked and the CoreID indicates which AHB bus master has locked it. The ProcessID indicates which process of that AHB bus master has locked the semaphore.

When Write locking a semaphore, the CoreID is taken from the master ID and the ProcessID is taken from the Write data. When Read locking the semaphore, the CoreID is taken from the master ID, and the ProcessID will be zero. There are no ProcessID available with the 1-step (Read) lock.

The CoreID is taken from the AHB bus master ID. The ProcessID is written by the firmware of that AHB bus master. Each AHB bus master process must have a unique ProcessID. ProcessID is only available in the 2-step lock procedure.

The two procedures (1-step and 2-step) can be used concurrently.

Figure 59. Procedure state diagram

**2-step (Write) lock procedure**

The 2-step lock procedure consists in a Write to lock the semaphore, followed by a Read to check if the lock has been successful, carried out from the HSEM\_Rn register

- Write semaphore with ProcessID and CoreID, and LOCK bit = 1 (Lock will be put in place when semaphore is free at Write time)
- Read-back the semaphore (FW checks lock status, if ProcessID and CoreID match, then lock is confirmed).
- Else retry (the semaphore has been locked by another AHB bus master or process)

A semaphore can only be locked when it is free.

A semaphore can be locked when the ProcessID is '0'.

Consecutive write attempts with the lock bit = 1 to a locked semaphore are ignored.

**1-step (Read) lock procedure**

The 1-step procedure consists in a Read to lock and check the semaphore in a single step from the HSEM\_RLRn register.

- Read Lock semaphore with CoreID.
- If Read CoreID matches and ProcessID = 0, then lock is put in place. (if CoreID matches and ProcessID is not '0', this means that another process from the same CoreID has locked the semaphore with a 2-step (Write) procedure).
- Else retry (the semaphore has been locked by another AHB bus master or process)

A semaphore can only be locked when it is free. When Read locking a free semaphore the ProcessID will be '0'. Read locking a locked semaphore will return the CoreID and ProcessID that locked it. All Read locks, including the first one which locks the semaphore, will return the CoreID that locks or has locked the semaphore.

If multiple processes of the same AHB bus master use the 1-step procedure, all processes using the same semaphore will read the same status. When only one process locks the semaphore, each process of that AHB bus master will read the semaphore as locked by itself with the CoreID.

### 10.3.4 HSEM Write/Read/ReadLock register address

For each semaphore, two AHB register addresses are provided, separated in two banks of 0x80.

In the first register address bank the semaphore can be written (locked/cleared) and read through the HSEM\_R registers.

In the second register address bank the semaphore can be read (locked) through the HSEM\_RLR registers.

### 10.3.5 HSEM Clear procedures

Clearing a semaphore is a protected process, to prevent accidental clearing by a AHB bus master or by a process that does not have the semaphore lock right. The semaphore Clear procedure consists in writing to the semaphore with the corresponding CoreID and ProcessID and the lock bit = 0. When cleared, the semaphore lock bit, the CoreID, and the ProcessID are all '0'.

When cleared, an interrupt may be generated to signal the event. To this end, the semaphore interrupt shall be enabled.

The Clear procedure consists in a Write to the semaphore HSEM\_R register

- Write semaphore with ProcessID and CoreID, lock bit = 0
- If ProcessID and CoreID match, semaphore is freed, and an interrupt may be generated when enabled
- Else Write is ignored, semaphore remains locked and no interrupts are generated (the semaphore is locked by another AHB bus master or process)

If multiple processes of the same AHB bus master use the 1-step lock procedure (ProcessID = 0), all processes using the same semaphore will clear the semaphore also for the other processes of that AHB bus master.

### 10.3.6 HSEM CoreID semaphore clear

All semaphores locked by a AHB bus master can be cleared all at once by using the HSEM\_CR register.

The procedure to clear all semaphores locked by a AHB bus master is the following:

- Write CoreID and correct KEY value. All locked semaphore with a matching CoreID are cleared (set to free), and may generate an interrupt when enabled.

This procedure may be used in case of an incorrect functioning AHB bus master, where another AHB bus master can free the locked semaphores by writing the incorrect functioning CoreID into the HSEM\_CR register with the correct KEY value. This will clear all locked semaphores with a matching CoreID.

An interrupt may be generated for the semaphore(s) that become free. To this end, the semaphore interrupt shall be enabled in the HSEM\_CnIER registers.

### 10.3.7 HSEM interrupts

There are two interrupt lines, hsem\_int1\_it (for interrupt 1) and hsem\_int2\_it (for interrupt 2), allowing each of the 32 semaphores to generate an interrupt.

Each of these two Interrupt lines provides the following features:

- Interrupt enable per semaphore
- Interrupt clear per semaphore
- Interrupt status per semaphore
- Masked interrupt status per semaphore

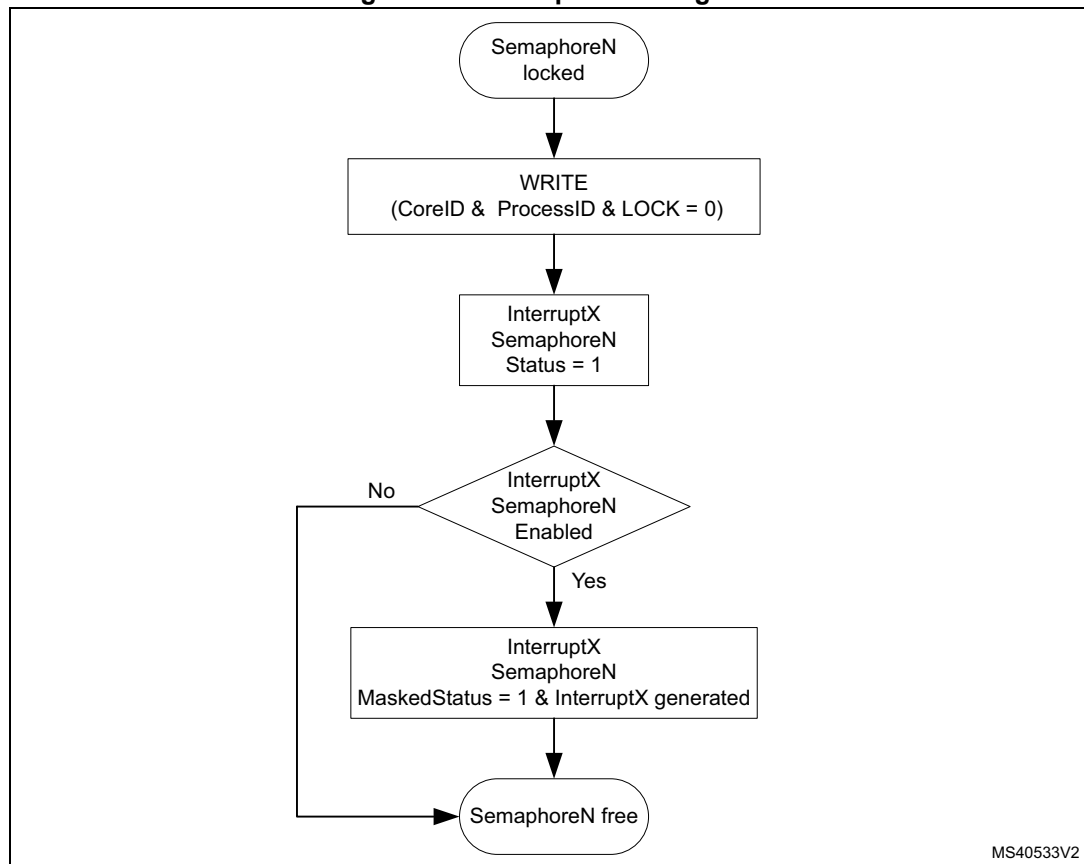

With the Interrupt enable (HSEM\_CnIER) the semaphores affecting the interrupt line can be enabled. Disabled (masked) semaphore interrupts will not set the masked interrupt status for that semaphore, and will not generate an interrupt on the interrupt line.

The Interrupt clear (HSEM\_CnICR) will clear the Interrupt status and Masked interrupt status of the associated semaphore for the interrupt line.

The Interrupt status (HSEM\_CnISR) mirrors the semaphore Interrupt status of the interrupt line before the Enable.

The Masked interrupt status (HSEM\_CnMISR) only mirrors the semaphore Interrupt status of the enabled semaphore interrupts on the interrupt line. All Masked interrupt status of the enabled semaphore need to be cleared in order to clear the interrupt line.

Figure 60. Interrupt state diagram

The procedure to get an interrupt when a semaphore becomes free is described hereafter.

### Try to lock the semaphore N

- If the semaphore lock is obtained, no interrupt is needed.
- If the semaphore lock fails:
  - Clear pending semaphore N interrupt status for the interrupt line hsem\_intn\_it in HSEM\_CnICR.
  - Re-try to lock the semaphore N again:
    - If the semaphore lock is obtained, no interrupt is needed (semaphore has been freed between first try to lock it and clear semaphore interrupt status).
    - If the semaphore lock fails, enable the semaphore N interrupt for the interrupt line hsem\_intnn\_it in HSEM\_CnIER.

### On the semaphore N free interrupt, try to lock the semaphore N

- If the semaphore lock is obtained:
  - disable the semaphore N interrupt for the interrupt line hsem\_intn\_it in HSEM\_CnIER, and clear pending semaphore N interrupt status for the interrupt line hsem\_intn\_it in HSEM\_CnICR.
- If the semaphore N lock fails:
  - Clear pending semaphore N Interrupt status for the interrupt line hsem\_intn\_it in HSEM\_CnICR.
  - Try again to lock the semaphore N:
    - If the semaphore lock is obtained (semaphore has been freed between first try to lock and semaphore Interrupt status clear):
      - Disable the semaphore interrupt for the interrupt line hsem\_intn\_it in HSEM\_CnIER.
    - If the semaphore lock failed, wait for semaphore free interrupt.

*Note: An interrupt will not lock the semaphore. After an interrupt either the AHB bus master or the process still have to perform the lock procedure to lock the semaphore.*

It is possible to have multiple AHB bus masters informed by the semaphore free interrupts. Each AHB bus master will get its interrupt, and the first one to react will lock the semaphore.

## 10.3.8 AHB bus master ID verification

The HSEM allows only authorized AHB bus master IDs to lock and unlock semaphores.

- The AHB bus master 2-step lock Write access to the semaphore HSEM\_Rn register is checked against the valid bus master IDs.
  - Accesses from unauthorized AHB bus master IDs are discarded and will not lock the semaphore.
- The AHB bus master 1-step lock Read access from the semaphore HSEM\_RLRn register is checked against the valid bus master IDs.
  - An unauthorized AHB bus master ID read from HSEM\_RLRn will return the following Read data depending on the semaphore status:

- when the semaphore is free it will return all '0's
- when the semaphore has been locked before it will return the HSEM\_RLRn data.
- The CoreID semaphore clears Write access to the HSEM\_CR register is checked against the valid bus master IDs. Only the valid bus master IDs can write to the HSEM\_CR register and clear any of the CoreID semaphores.
  - Accesses from unauthorized AHB bus master IDs are discarded and will not clear the CoreID semaphore.

Table 81 details the relation between bus master/CPU and COREID.

**Table 81. Authorized AHB bus master IDs**

Bus master 0 (CPU1)	Bus master 1 (CPU2)
COREID = 3	COREID = 1

*Note:* Accesses from unauthorized AHB bus master IDs to other registers are granted.

## 10.4 HSEM registers

Registers shall be accessed using Word format. Byte and Half Word access are ignored and will have no effect on the semaphores. Byte and Half Word Read accesses will always return 0. Byte and Half Word accesses will not generate a bus error.

### 10.4.1 HSEM register (HSEM\_R0 - HSEM\_R31)

Address offset: 0x000 + N x 4 (where N = Semaphore number 0 - 31)

Reset value: 0x0000 0000

The HSEM\_R0 - HSEM\_R31 shall be used to perform a 2-step Write lock and Read back. Only Write accesses with authorized AHB bus master IDs are granted. Write accesses with unauthorized AHB bus master IDs are discarded.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	COREID				PROCID							
				rw	rw	rw	rw	rw							

Bit 31 **LOCK**: Lock indication.

This bit can be written and read by firmware.

0: On Write free semaphore (only when COREID and PROCID match), on Read semaphore is free.

1: On Write try to lock semaphore, on Read semaphore is locked.

Bits 30:12 Reserved, must be kept at reset value

Bits 11:8 **COREID**: Semaphore CoreID.

Written by firmware, when the semaphore is free and the LOCK bit is at the same time written to 1, the COREID will be written only when the bus ID of the AHB bus master writing the semaphore matches.

When the semaphore is cleared (LOCK bit written to 0 and AHB bus master ID matched COREID), the CoreID will be cleared to 0.

When the semaphore is cleared (LOCK bit written to 0 and AHB bus master ID does not match COREID), the CoreID will not be affected.

Write when LOCK bit is already 1 (semaphore locked), the CoreID will not be affected.

A Read will return the stored CoreID value.

Bits 7:0 **PROCID**: Semaphore ProcessID.

Written by firmware, when the semaphore is free and the lock bit is written to 1, the ProcessID will be set to the written data.

When the semaphore is cleared, (LOCK bit written to 0), the ProcessID will be cleared to 0.

Write when LOCK bit is already 1 (semaphore locked), the ProcessID will not be affected.

A Read will return the programmed ProcessID value.

### 10.4.2 HSEM Read lock register (HSEM\_RLR0 - HSEM\_RLR31)

Address offset: 0x080 + N x 4 (where N = Semaphore number 0 - 31)

Reset value: 0x0000 0000

Accesses the same physical bits as HSEM\_R0 - HSEM\_R31. The HSEM\_RLR0 - HSEM\_RLR31 shall be used to perform a 1-step Read lock. Only Read accesses with authorized AHB bus master IDs are granted. Read accesses with unauthorized AHB bus master IDs are discarded.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	COREID				PROCID							
				r	r	r	r	r							

Bit 31 **LOCK**: Lock indication.

This bit is read only by firmware at this address. A Read with a valid bus master ID will always return 1.

When the semaphore is free and the firmware performs a Read, hardware will set the semaphore to locked.

When the semaphore is locked and the firmware performs a Read the LOCK bit is not effected.

0: Semaphore is free.

1: Semaphore is locked.

Bits 30:12 Reserved, must be kept at reset value

Bits 11:8 **COREID**: Semaphore CoreID.

This field is read only by firmware at this address.

On a Read, when the semaphore is free, hardware will set the CoreID to the AHB bus master ID reading the semaphore. The CoreID of the AHB bus master locking the semaphore will be read.

On a Read when the semaphore is locked, will return the CoreID of the AHB bus master that has locked the semaphore.

Bits 7:0 **PROCID**: Semaphore ProcessID.

This field is read only by firmware at this address.

On a Read when the semaphore is free will return 0.

On a Read when the semaphore is locked will return the ProcessID of the process that has locked the semaphore.

### 10.4.3 HSEM Interrupt enable register (HSEM\_CnIER)

Address offset:  $0x100 + (N - 1) \times 0x10$  (where N = Interrupt number 1 - 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ISE[31:16]

ISE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ISEn**: Interrupt(N) semaphore n enable bit.

This bit is read and written by firmware.

0: Interrupt(N) generation for semaphore n is disabled (masked).

1: Interrupt(N) generation for semaphore n is enabled (not masked).

### 10.4.4 HSEM Interrupt clear register (HSEM\_CnICR)

Address offset:  $0x104 + (N - 1) \times 0x10$  (where N = Interrupt number 1 - 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ISC[15:0]															
wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0	wr0

Bits 31:0 **ISCn**: Interrupt(N) semaphore n clear bit.

This bit is written by firmware, and will always read 0.

0: Interrupt(N) semaphore n status and masked status not affected.

1: Interrupt(N) semaphore n status and masked status cleared.

### 10.4.5 HSEM Interrupt status register (HSEM\_CnISR)

Address offset:  $0x108 + (N - 1) \times 0x10$  (where N = Interrupt number 1 - 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ISF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ISFn**: Interrupt(N) semaphore n status bit before enable (mask).

This bit is set by hardware and read only by firmware.

Bit will be cleared by firmware writing the corresponding HSEM\_CnICR bit.

0: Interrupt(N) semaphore n status, no interrupt pending.

1: Interrupt(N) semaphore n status, interrupt pending.

### 10.4.6 HSEM Masked interrupt status register (HSEM\_CnMISR)

Address offset: 0x10C + (N - 1) x 0x10 (where N = Interrupt number 1 - 2)

Reset value: 0x0000 0000

MISF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **MISFn**: masked interrupt(N) semaphore n status bit after enable (mask).

This bit is set by hardware and read only by firmware.

Bit will be cleared by firmware writing the corresponding HSEM\_CnICR bit.

0: Interrupt(N) semaphore n status after masking not pending.

1: Interrupt(N) semaphore n status after masking pending.

### 10.4.7 HSEM Clear register (HSEM\_CR)

Address offset: 0x140

Reset value: 0x0000 0000

Only Write accesses with authorized AHB bus master IDs are granted. Write accesses with unauthorized AHB bus master IDs are discarded.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				wr0												

Bits 31:16 **KEY**: Semaphore clear Key.

This bit can be written by firmware. Will always read 0.

Key value not matching HSEM\_KEYR.KEY, semaphores not effected.

Key value matching HSEM\_KEYR.KEY, all semaphores matching the COREID will be cleared to the free state.

Bits 15:12 Reserved, must be kept at reset value

Bits 11:8 **COREID**: CoreID of semaphores to be cleared.

This field can be written by firmware, will always read 0.

Indicates the CoreID for which the semaphores will be cleared when writing the HSEM\_CR.

Bits 7:0 Reserved, must be kept at reset value

### 10.4.8 HSEM Interrupt clear register (HSEM\_KEYR)

Address offset: 0x144

Reset value: 0x0000 0000

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

# 11 General-purpose I/Os (GPIO)

## 11.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR and GPIOx\_PUPDR), two 32-bit data registers (GPIOx\_IDR and GPIOx\_ODR) and a 32-bit set/reset register (GPIOx\_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx\_LCKR) and two 32-bit alternate function selection registers (GPIOx\_AFRH and GPIOx\_AFLR).

## 11.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx\_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx\_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx\_BSRR) for bitwise write access to GPIOx\_ODR
- Locking mechanism (GPIOx\_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

## 11.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx\_BSRR and GPIOx\_BRR registers is to allow atomic read/modify accesses to any of the GPIOx\_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 61 and Figure 62 show the basic structures of a standard and a 5 V tolerant I/O port bit, respectively. Table 83 gives the possible port bit configurations.

Figure 61. Basic structure of an I/O port bit

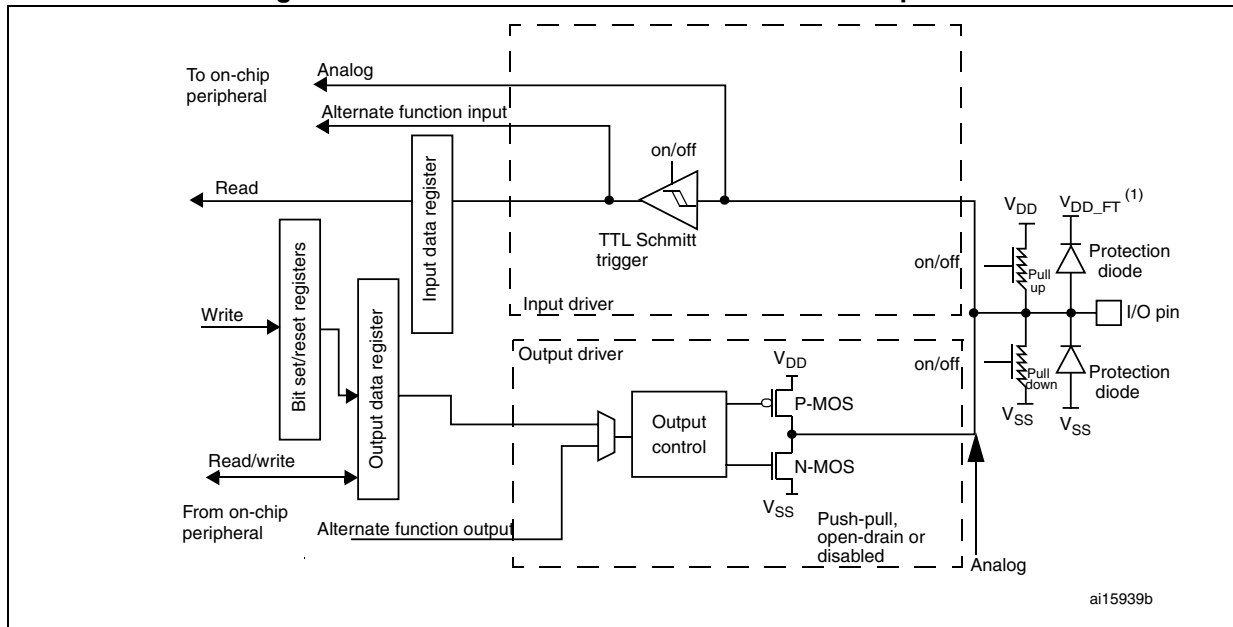

Figure 62. Basic structure of a five-volt tolerant I/O port bit

1.  $V_{DD\_FT}$  is a potential specific to five-volt tolerant I/Os and different from  $V_{DD}$ .

Table 83. Port bit configuration table<sup>(1)</sup>

MODE(i) [1:0]	OTYPER(i)	OSPEED(i) [1:0]		PUPD(i) [1:0]		I/O configuration	
01	0	SPEED [1:0]		0	0	GP output	PP
	0			0	1	GP output	PP + PU
	0			1	0	GP output	PP + PD
	0			1	1	Reserved	
	1			0	0	GP output	OD
	1			0	1	GP output	OD + PU
	1			1	0	GP output	OD + PD
	1			1	1	Reserved (GP output OD)	
10	0	SPEED [1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

### 11.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in input floating mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state

When the pin is configured as output, the value written to the output data register (GPIOx\_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx\_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx\_PUPDR register.

### 11.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx\_AFRL (for pin 0 to 7) and GPIOx\_AFRH (for pin 8 to 15) registers:

- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx\_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.
- Cortex-M7 with FPU EVENTOUT is mapped on AF15

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:

- **Debug function:** after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **System function:** MCOx pins have to be configured in alternate function mode.
- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx\_MODER register.
- **Peripheral alternate function:**
  - Connect the I/O to the desired AFx in one of the GPIOx\_AFRL or GPIOx\_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx\_OTYPER, GPIOx\_PUPDR and GPIOx\_OSPEEDER registers, respectively.

- Configure the desired I/O as an alternate function in the GPIOx\_MODER register.
- **Additional functions:**
  - For the ADC and DAC, configure the desired I/O in analog mode in the GPIOx\_MODER register and configure the required function in the ADC and DAC registers.
  - For the additional functions like RTC\_OUT, RTC\_TS, RTC\_TAMPx, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers. For details about I/O control by the RTC, refer to [Section 46.3: RTC functional description on page 1831](#).
- EVENTOUT
  - Configure the I/O pin used to output the core EVENTOUT signal by connecting it to AF15.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

### 11.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR) to configure up to 16 I/Os. The GPIOx\_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx\_OTYPER and GPIOx\_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx\_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 11.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx\_IDR and GPIOx\_ODR). GPIOx\_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx\_IDR), a read-only register.

See [Section 11.4.5: GPIO port input data register \(GPIOx\\_IDR\) \(x = A..K\)](#) and [Section 11.4.6: GPIO port output data register \(GPIOx\\_ODR\) \(x = A..K\)](#) for the register descriptions.

### 11.3.5 I/O data bitwise handling

The bit set reset register (GPIOx\_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx\_ODR). The bit set reset register has twice the size of GPIOx\_ODR.

To each bit in GPIOx\_ODR, correspond two control bits in GPIOx\_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) **sets** the corresponding ODR(i) bit. When written to 1, bit BR(i) **resets** the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx\_BSRR does not have any effect on the corresponding bit in GPIOx\_ODR. If there is an attempt to both set and reset a bit in GPIOx\_BSRR, the set action takes priority.

Using the GPIOx\_BSRR register to change the values of individual bits in GPIOx\_ODR is a “one-shot” effect that does not lock the GPIOx\_ODR bits. The GPIOx\_ODR bits can always

be accessed directly. The GPIOx\_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx\_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

### 11.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx\_LCKR register. The frozen registers are GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH.

To write the GPIOx\_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx\_LCKR bit freezes the corresponding bit in the control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH).

The LOCK sequence (refer to [Section 11.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A..K\)](#)) can only be performed using a word (32-bit long) access to the GPIOx\_LCKR register due to the fact that GPIOx\_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in [Section 11.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A..K\)](#).

### 11.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx\_AFRL and GPIOx\_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

### 11.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode. Refer to [Section 20: Extended interrupt and event controller \(EXTI\)](#) and to [Section 20.3: EXTI functional description](#).

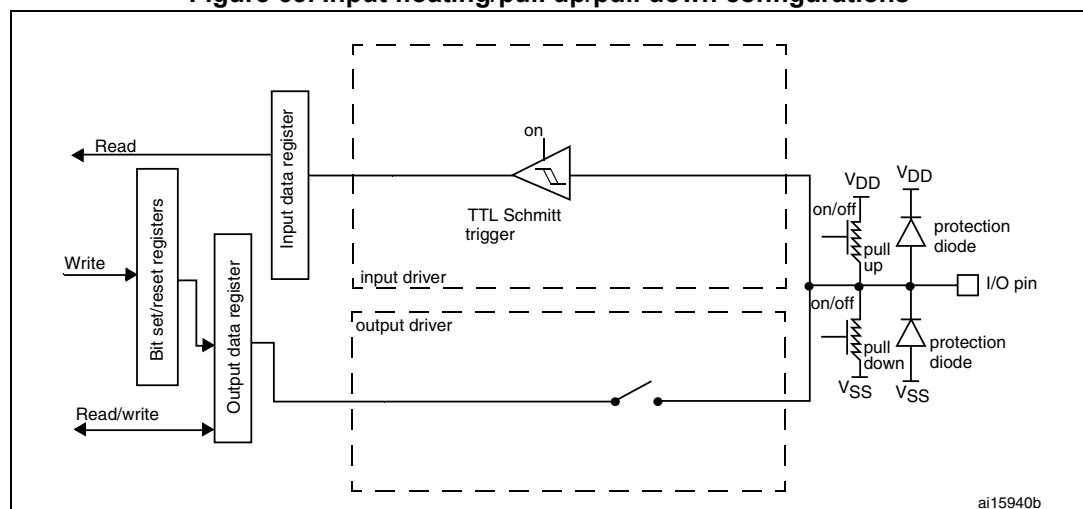

### 11.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

Figure 63 shows the input configuration of the I/O port bit.

Figure 63. Input floating/pull up/pull down configurations

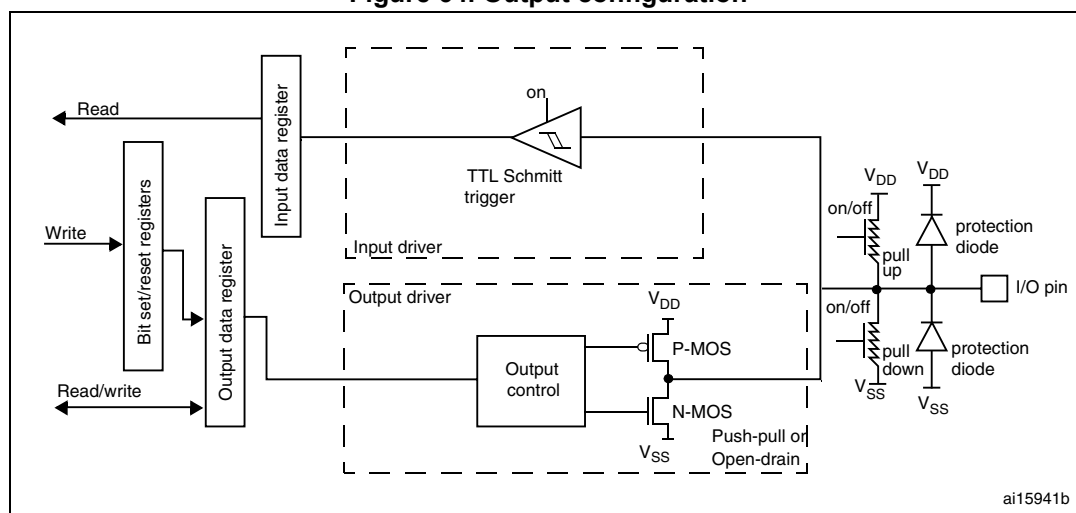

### 11.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

Figure 64 shows the output configuration of the I/O port bit.

Figure 64. Output configuration

### 11.3.11 I/O compensation cell

This cell is used to control the I/O commutation slew rate ( $t_{fall}$  /  $t_{rise}$ ) to reduce the I/O noise on power supply.

The cell is split into two blocks:

- The first block provides an optimal code for the current PVT. The code stored in this block can be read when the READY flag of the SYSCFG\_CCSR is set.
- The second block controls the I/O slew rate. The user selects the code to be applied and programs it by software.

The I/O compensation cell features 2 voltage ranges: 1.62 to 2.0 V and 2.7 to 3.6 V.

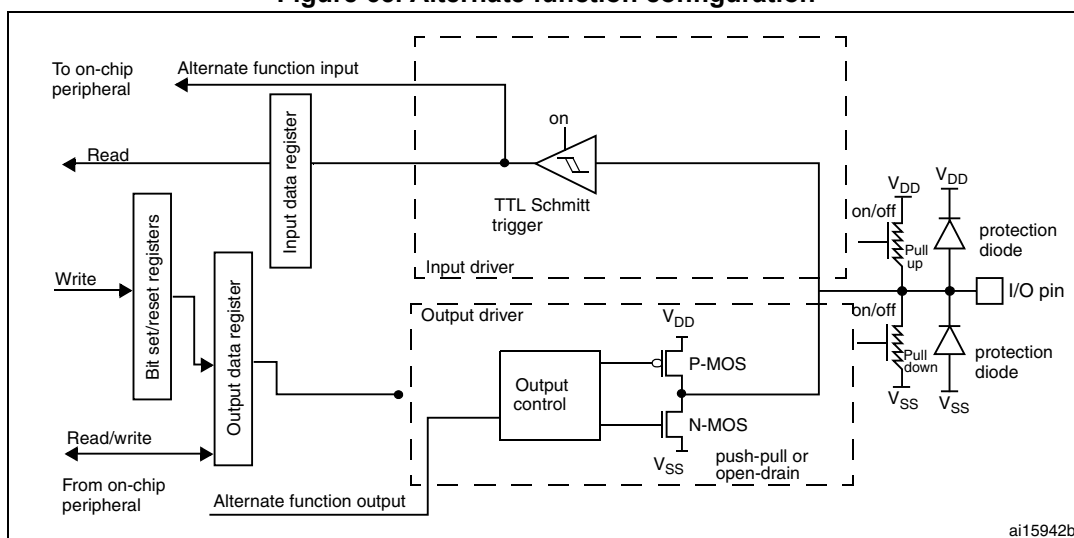

### 11.3.12 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

*Figure 65* shows the Alternate function configuration of the I/O port bit.

Figure 65. Alternate function configuration

### 11.3.13 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value "0"

Figure 66 shows the high-impedance, analog-input configuration of the I/O port bit.

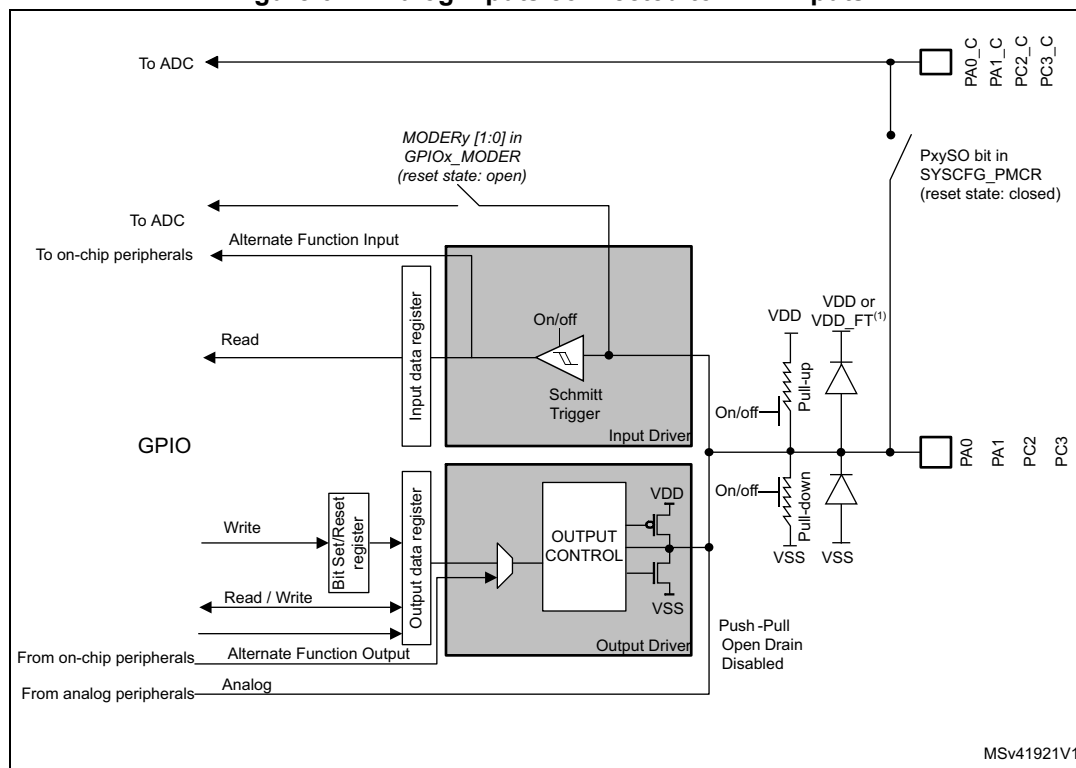

Figure 66. High impedance-analog configuration

Some pins/balls are directly connected to PA0\_C, PA1\_C, PC2\_C and PC3\_C ADC analog inputs (see Figure 67): there is a direct path between Pxy\_C and Pxy pins/balls, through an

analog switch (refer to [Section 12.3.1: SYSCFG peripheral mode configuration register \(SYSCFG\\_PMCr\)](#) for details on how to configure analog switches).

**Figure 67. Analog inputs connected to ADC inputs**

1. VDD\_FT is a potential specific to 5V tolerant I/Os. It is distinct from VDD.

### 11.3.14 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC\_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the OSC\_IN or OSC32\_IN pin is reserved for clock input and the OSC\_OUT or OSC32\_OUT pin can still be used as normal GPIO.

### 11.3.15 Using the GPIO pins in the backup supply domain

The PC13/PC14/PC15/PI8 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

[Section 46.3: RTC functional description on page 1836.](#)

## 11.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to [Table 84](#).

The peripheral registers can be written in word, half word or byte mode.

### 11.4.1 GPIO port mode register (GPIOx\_MODER) (x =A..K)

Address offset:0x00

Reset values:

- 0xABFF FFFF for port A
- 0xFFFF FEBF for port B
- 0xFFFF FFFF for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODER15[1:0]		MODER14[1:0]		MODER13[1:0]		MODER12[1:0]		MODER11[1:0]		MODER10[1:0]		MODER9[1:0]		MODER8[1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODER7[1:0]		MODER6[1:0]		MODER5[1:0]		MODER4[1:0]		MODER3[1:0]		MODER2[1:0]		MODER1[1:0]		MODER0[1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 2y+1:2y **MODERy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O mode.

- 00: Input mode (reset state)
- 01: General purpose output mode
- 10: Alternate function mode
- 11: Analog mode

### 11.4.2 GPIO port output type register (GPIOx\_OTYPER) (x = A..K)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O output type.

- 0: Output push-pull (reset state)
- 1: Output open-drain

### 11.4.3 GPIO port output speed register (GPIOx\_OSPEEDR) (x = A..K)

Address offset: 0x08

Reset value:

- 0x0C00 0000 for port A
- 0x0000 00C0 for port B
- 0x0000 0000 for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEEDR15 [1:0]		OSPEEDR14 [1:0]		OSPEEDR13 [1:0]		OSPEEDR12 [1:0]		OSPEEDR11 [1:0]		OSPEEDR10 [1:0]		OSPEEDR9 [1:0]		OSPEEDR8 [1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 2y+1:2y **OSPEEDRy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O output speed.

- 00: Low speed
- 01: Medium speed
- 10: High speed
- 11: Very high speed

*Note: Refer to the product datasheets for the values of OSPEEDRy bits versus V<sub>DD</sub> range and external load.*

### 11.4.4 GPIO port pull-up/pull-down register (GPIOx\_PUPDR) (x = A..K)

Address offset: 0x0C

Reset values:

- 0x6400 0000 for port A
- 0x0000 0100 for port B
- 0x0000 0000 for other ports

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPDR15[1:0]		PUPDR14[1:0]		PUPDR13[1:0]		PUPDR12[1:0]		PUPDR11[1:0]		PUPDR10[1:0]		PUPDR9[1:0]		PUPDR8[1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

PUPDR7[1:0]		PUPDR6[1:0]		PUPDR5[1:0]		PUPDR4[1:0]		PUPDR3[1:0]		PUPDR2[1:0]		PUPDR1[1:0]		PUPDR0[1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 2y+1:2y **PUPDRy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

### 11.4.5 GPIO port input data register (GPIOx\_IDR) (x = A..K)

Address offset: 0x10

Reset value: 0x0000 XXXX (where X means undefined)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR15	IDR14	IDR13	IDR12	IDR11	IDR10	IDR9	IDR8	IDR7	IDR6	IDR5	IDR4	IDR3	IDR2	IDR1	IDR0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDRy**: Port input data bit (y = 0..15)

These bits are read-only. They contain the input value of the corresponding I/O port.

### 11.4.6 GPIO port output data register (GPIOx\_ODR) (x = A..K)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ODR15	ODR14	ODR13	ODR12	ODR11	ODR10	ODR9	ODR8	ODR7	ODR6	ODR5	ODR4	ODR3	ODR2	ODR1	ODR0
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODRy**: Port output data bit (y = 0..15)

These bits can be read and written by software.

*Note: For atomic bit set/reset, the ODR bits can be individually set and/or reset by writing to the GPIOx\_BSRR or GPIOx\_BRR registers (x = A..F).*

### 11.4.7 GPIO port bit set/reset register (GPIOx\_BSRR) (x = A..K)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy**: Port x reset bit y (y = 0..15)  
 These bits are write-only. A read to these bits returns the value 0x0000.  
 0: No action on the corresponding ODRx bit  
 1: Resets the corresponding ODRx bit  
*Note: If both BSx and BRx are set, BSx has priority.*

Bits 15:0 **BSy**: Port x set bit y (y= 0..15)  
 These bits are write-only. A read to these bits returns the value 0x0000.  
 0: No action on the corresponding ODRx bit  
 1: Sets the corresponding ODRx bit

### 11.4.8 GPIO port configuration lock register (GPIOx\_LCKR) (x = A..K)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

*Note: A specific write sequence is used to write to the GPIOx\_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.*

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK**: Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx\_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:

WR LCKR[16] = '1' + LCKR[15:0]

WR LCKR[16] = '0' + LCKR[15:0]

WR LCKR[16] = '1' + LCKR[15:0]

RD LCKR

RD LCKR[16] = '1' (this read operation is optional but it confirms that the lock is active)

*Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.*

*Any error in the lock sequence aborts the lock.*

*After the first lock sequence on any bit of the port, any read access on the LCKK bit will return '1' until the next MCU reset or peripheral reset.*

Bits 15:0 **LCKy**: Port x lock bit y (y= 0..15)

These bits are read/write but can only be written when the LCKK bit is '0'.

0: Port configuration not locked

1: Port configuration locked

### 11.4.9 GPIO alternate function low register (GPIOx\_AFRL) (x = A..K)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 12 System configuration controller (SYSCFG)

### 12.1 Introduction

The devices feature a set of configuration registers. The objectives of this section is to describe in details the system configuration controller.

### 12.2 SYSCFG main features

The system configuration controller main functions are the following:

- Analog switch configuration management
- I2C Fm+ configuration
- Selection of the Ethernet PHY interface.
- Management of the external interrupt line connection to the GPIOs
- Management of the I/O compensation cell
- Getting readout protection and Flash memory bank swap informations
- Management of boot sequences and boot addresses
- Management BOR reset level
- Management of Flash memory secured and protected sector status
- Management Flash memory write protections status
- Management of DTCM secured section status
- Management of independent watchdog behavior (hardware or software / freeze)
- Reset generation in Stop and Standby mode
- Secure mode enabling/disabling.

### 12.3 SYSCFG register description

#### 12.3.1 SYSCFG peripheral mode configuration register (SYSCFG\_PMCR)

Address offset: 0x04

Reset value: 0x0X00 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	PC3SO	PC2SO	PA1SO	PA0SO	EPIS[2:0]			Res.	Res.	Res.	Res.	Res.
				rw	rw	rw	rw	rw	rw	rw					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOSTE	PB9 FMP	PB8 FMP	PB7 FMP	PB6 FMP	I2C4 FMP	I2C3 FMP	I2C2 FMP	I2C1 FMP
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **PC3SO**: PC3 Switch Open

This bits controls the analog switch between PC3 and PC3\_C (dual pad)  
0: Analog switch closed (pads are connected through the analog switch)  
1: Analog switch open (2 separated pads)

Bit 26 **PC2SO**: PC2 Switch Open

This bits controls the analog switch between PC2 and PC2\_C (dual pad)  
0: Analog switch closed (pads are connected through the analog switch)  
1: Analog switch open (2 separated pads)

Bit 25 **PA1SO**: PA1 Switch Open

This bits controls the analog switch between PA1 and PA1\_C (dual pad)  
0: Analog switch closed (pads are connected through the analog switch)  
1: Analog switch open (2 separated pads)

Bit 24 **PA0SO**: PA0 Switch Open

This bits controls the analog switch between PA0 and PA0\_C (dual pad)  
0: Analog switch closed (pads are connected through the analog switch)  
1: Analog switch open (2 separated pads)

Bits 23:21 **EPIS[2:0]**: Ethernet PHY Interface Selection

These bits select the Ethernet PHY interface.

000: MII  
001: Reserved  
010: Reserved  
011: Reserved  
100: RMI  
101: Reserved  
110: Reserved  
111: Reserved

Bits 20:9 Reserved, must be kept at reset value.

Bit 8 **BOOSTE**: Booster Enable

This bit enables the booster to reduce the total harmonic distortion of the analog switch when the supply voltage is lower than 2.7 V.  
Activating the booster allows to guaranty the analog switch AC performance when the supply voltage is below 2.7 V: in this case, the analog switch performance is the same on the full voltage range.  
0: Booster disabled  
1: Booster enabled

Bit 7 **PB9FMP**: PB(9) Fm+

This bit enables I2C Fm+ on PB(9).  
0: Fm+ disabled  
1: Fm+ enabled

Bit 6 **PB8FMP**: PB(8) Fast Mode Plus

This bit enables I2C Fm+ on PB(8).  
0: Fm+ disabled  
1: Fm+ enabled

- Bit 5 **PB7FMP**: PB(7) Fast Mode Plus  
 this bit enables I2C Fm+ on PB(7).  
 0: Fm+ disabled  
 1: Fm+ enabled
- Bit 4 **PB6FMP**: PB(6) Fm+  
 This bit enables I2C Fm+ on PB(6).  
 0: Fm+ disabled  
 1: Fm+ enabled
- Bit 3 **I2C4FMP**: I2C4 Fm+  
 This bit enables Fm+ on I2C4.  
 0: Fm+ disabled  
 1: Fm+ enabled
- Bit 2 **I2C3FMP**: I2C3 Fm+  
 This bit enables Fm+ on I2C3.  
 0: Fm+ disabled  
 1: Fm+ enabled
- Bit 1 **I2C2FMP**: I2C2 Fm+  
 This bit enables Fm+ on I2C2.  
 0: Fm+ disabled  
 1: Fm+ enabled
- Bit 0 **I2C1FMP**: I2C1 Fm+  
 This bit enables Fm+ on I2C1.  
 0: Fm+ disabled  
 1: Fm+ enabled

### 12.3.2 SYSCFG external interrupt configuration register 1 (SYSCFG\_EXTICR1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI3[3:0]				EXTI2[3:0]				EXTI1[3:0]				EXTI0[3:0]			
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 0 to 3)

These bits are written by software to select the source input for the EXTI input for external interrupt / event detection.

- 0000: PA[x] pin
- 0001: PB[x] pin
- 0010: PC[x] pin
- 0011: PD[x] pin
- 0100: PE[x] pin
- 0101: PF[x] pin
- 0110: PG[x] pin
- 0111: PH[x] pin
- 1000: PI[x] pin
- 1001: PJ[x] pin
- 1010: PK[x] pin

Other configurations: reserved

### 12.3.3 SYSCFG external interrupt configuration register 2 (SYSCFG\_EXTICR2)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI7[3:0]				EXTI6[3:0]				EXTI5[3:0]				EXTI4[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 4 to 7)

These bits are written by software to select the source input for the EXTI input for external interrupt / event detection.

- 0000: PA[x] pin
- 0001: PB[x] pin
- 0010: PC[x] pin
- 0011: PD[x] pin
- 0100: PE[x] pin
- 0101: PF[x] pin
- 0110: PG[x] pin
- 0111: PH[x] pin
- 1000: PI[x] pin
- 1001: PJ[x] pin
- 1010: PK[x] pin

Other configurations: reserved

### 12.3.4 SYSCFG external interrupt configuration register 3 (SYSCFG\_EXTICR3)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI11[3:0]				EXTI10[3:0]				EXTI9[3:0]				EXTI8[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 8 to 11)

These bits are written by software to select the source input for the EXTI input for external interrupt / event detection.

- 0000: PA[x] pin
- 0001: PB[x] pin
- 0010: PC[x] pin
- 0011: PD[x] pin
- 0100: PE[x] pin
- 0101: PF[x] pin
- 0110: PG[x] pin
- 0111: PH[x] pin
- 1000: PI[x] pin
- 1001: PJ[x] pin
- 1010: PK[x] pin

Other configurations: reserved

*Note: PK[11:8] are not used*

### 12.3.5 SYSCFG external interrupt configuration register 4 (SYSCFG\_EXTICR4)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTI15[3:0]				EXTI14[3:0]				EXTI13[3:0]				EXTI12[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 12 to 15)

These bits are written by software to select the source input for the EXTI input for external interrupt / event detection.

- 0000: PA[x] pin
- 0001: PB[x] pin
- 0010: PC[x] pin
- 0011: PD[x] pin
- 0100: PE[x] pin
- 0101: PF[x] pin
- 0110: PG[x] pin
- 0111: PH[x] pin
- 1001: PJ[x] pin
- 1010: PK[x] pin

Other configurations: reserved

Note: PK[15:12] are not used.

### 12.3.6 SYSCFG compensation cell control/status register (SYSCFG\_CCCSR)

Address offset: 0x20

Reset value: 0x0000 0000

Refer to [Section 11.3.11: I/O compensation cell](#) for a detailed description of I/O compensation mechanism.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSLV
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	READY	Res.	Res.	Res.	Res.	Res.	Res.	CS	EN
							r							rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **HSLV**: High-speed at low-voltage

This bit is written by software to optimize the I/O speed when the product voltage is low.

This bit is active only if IO\_HSLV user option bit is set. It must be used only if the product supply voltage is below 2.5 V. Setting this bit when V<sub>DD</sub> is higher than 2.5 V might be destructive.

0: No I/O speed optimization  
 1: I/O speed optimization

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **READY**: Compensation cell ready flag

This bit provides the status of the compensation cell.

0: I/O compensation cell not ready  
 1: I/O compensation cell ready

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CS**: Code selection

This bit selects the code to be applied for the I/O compensation cell.

0: Code from the cell (available in the SYSCFG\_CCVR)  
 1: Code from the SYSCFG compensation cell code register (SYSCFG\_CCCR)

Bit 0 **EN**: Enable

This bit enables the I/O compensation cell.

0: I/O compensation cell disabled  
 1: I/O compensation cell enabled

### 12.3.7 SYSCFG compensation cell value register (SYSCFG\_CCVR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCV[3:0]				NCV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **PCV[3:0]**: PMOS compensation value

This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG\_CMPCR is reset.

Bits 3:0 **NCV[3:0]**: NMOS compensation value

This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG\_CMPCR is reset.

### 12.3.8 SYSCFG compensation cell code register (SYSCFG\_CCCR)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCC[3:0]				NCC[3:0]			
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **PCC[3:0]**: PMOS compensation code

This bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG\_CMPCR is set.

Bits 3:0 **NCC[3:0]**: NMOS compensation code

This bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG\_CCCSR is set.

### 12.3.9 SYSCFG package register (SYSCFG\_PKGR)

Address offset: 0x124

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PKG			
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PKG[3:0]**: Package

This bits indicate the device package.

0000: LQFP100 (STM32H7x3)

0010: TQFP144 (STM32H7x3)

0101: TQFP176/UFPGA176 (STM32H7x3)

1000: LQFP208/TFBGA240 (STM32H7x3)

Other configurations: all pads enabled

### 12.3.10 SYSCFG user register 0 (SYSCFG\_UR0)

Address offset: 0x300

Reset value: 0x00XX 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDP[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BKS
															r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RDP[7:0]**: Readout protection

This bits indicate the readout protection level.

0xAA: Level 0 (no protection)

0xCC: Level 2 (Flash memory readout protected, full debug features, boot from SRAM and boundary scan disabled)

Other configurations: Level 1 (Flash memory readout protected, limited debug features and boundary scan enabled)

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **BKS**: Bank Swap

This bit indicates Flash memory bank mapping.

0: Flash memory bank addresses are inverted

1: Flash memory banks are mapped to their original addresses

### 12.3.11 SYSCFG user register 2 (SYSCFG\_UR2)

Address offset: 0x308

Reset value: 0xFFFF 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOT_ADD0[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BORH[1:0]	
														r	r

Bits 31:16 **BOOT\_ADD0[15:0]**: Boot Address 0

These bits define the MSB of the core boot address when BOOT pin is low.

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 **BORH[1:0]**: BOR\_LVL Brownout Reset Threshold Level

These bits indicate the Brownout reset high level.

0x11: BOR High Reset Level threshold for 2.7-3.6 V range

0x10: BOR Medium Reset Level threshold for 2.4-2.7 V range

0x01: BOR Low Reset Level threshold for 2.1-2.4 V range

0x00: BOR OFF Reset Level threshold for 2.7-3.6 range

### 12.3.12 SYSCFG user register 3 (SYSCFG\_UR3)

Address offset: 0x30C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT_ADD1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BOOT\_ADD1[15:0]**: Boot Address 1

These bits define the MSB of the core boot address when BOOT pin is high.

### 12.3.13 SYSCFG user register 4 (SYSCFG\_UR4)

Address offset: 0x310

Reset value: 0x000X XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MEPAD_1
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **MEPAD\_1**: Mass Erase Protected Area Disabled for bank 1

This bit indicates if the flash protected area (Bank 1) is affected by a mass erase.

0: When a mass erase occurs the protected area is erased

1: When a mass erase occurs the protected area is not erased

Bits 15:0 Reserved, must be kept at reset value.

### 12.3.14 SYSCFG user register 5 (SYSCFG\_UR5)

Address offset: 0x314

Reset value: 0x00XX 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPS_1[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MESAD_1
															r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **WRPN\_1[7:0]**: Write protection for flash bank 1  
 WRPN[i] bit indicates if the sector i of the Flash memory bank 1 is protected.  
 0: Write protection is active on sector i  
 1: Write protection is not active on sector i

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MESAD\_1**: Mass erase secured area disabled for bank 1  
 This bit indicates if the flash secured area (bank 1) is affected by a mass erase.  
 0: When a mass erase occurs the secured area is erased  
 1: When a mass erase occurs the secured area is not erased

### 12.3.15 SYSCFG user register 6 (SYSCFG\_UR6)

Address offset: 0x318

Reset value: 0x0XXX 0XXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	PA_END_1[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PA_BEG_1[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 23:16 **PA\_END\_1[11:0]**: Protected area end address for bank 1  
 End address for bank 1 protected area.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PA\_BEG\_1[11:0]**: Protected area start address for bank 1  
 Start address for bank 1 protected area.

### 12.3.16 SYSCFG user register 7 (SYSCFG\_UR7)

Address offset: 0x31C

Reset value: 0x0XXX 0XXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	SA_END_1[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	SA_BEG_1[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 23:16 **SA\_END\_1[11:0]**: Secured area end address for bank 1  
End address for bank 1 secured area.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SA\_BEG\_1[11:0]**: Secured area start address for bank 1  
Start address for bank 1 secured area.

### 12.3.17 SYSCFG user register 8 (SYSCFG\_UR8)

Address offset: 0x320

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MESAD_2
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MEPAD_2
															r

Bits 31:17 Reserved, must be kept at reset value.

Bit 0 **MESAD\_2**: Mass erase secured area disabled for bank 2  
This bit indicates if the Flash memory secured area (Bank 2) is affected by a mass erase.  
0: When a mass erase occurs the secured area is erased  
1: When a mass erase occurs the secured area is not erased

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MEPAD\_2**: Mass erase protected area disabled for bank 2  
This bit indicates if the Flash memory protected area (Bank 2) is affected by a mass erase.  
0: When a mass erase occurs the protected area is erased  
1: When a mass erase occurs the protected area is not erased

### 12.3.18 SYSCFG user register 9 (SYSCFG\_UR9)

Address offset: 0x324

Reset value: 0x0XXX 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	PA_BEG_2[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPS_2[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **PA\_BEG\_2[11:0]**: Protected area start address for bank 2  
Start address for bank 2 protected area.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPN\_2[7:0]**: Write protection for flash bank 2  
WRPN[i] bit indicates if the sector i of the Flash memory bank 2 is protected.  
0: Write protection is active on sector i  
1: Write protection is not active on sector i

### 12.3.19 SYSCFG user register 10 (SYSCFG\_UR10)

Address offset: 0x328

Reset value: 0x0XXX 0XXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	SA_BEG_2[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PA_END_2[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SA\_BEG\_2[11:0]**: Secured area start address for bank 2  
Start address for bank 2 secured area.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PA\_END\_2[11:0]**: Protected area end address for bank 2  
End address for bank 2 protected area.

### 12.3.20 SYSCFG user register 11 (SYSCFG\_UR11)

Address offset: 0x32C

Reset value: 0x000X 0XXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IWDG1M
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	SA_END_2[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IWDG1M**: Independent Watchdog 1 mode

This bit indicates the control mode of the Independent Watchdog 1 (IWDG1).

0: IWDG1 controlled by software

1: IWDG1 controlled by hardware

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SA\_END\_2[11:0]**: Secured area end address for bank 2

End address for bank 2 secured area.

### 12.3.21 SYSCFG user register 12 (SYSCFG\_UR12)

Address offset: 0x330

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SECURE
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
															r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SECURE**: Secure mode

This bit indicates the Secure mode status.

0: Secure mode disabled

1: Secure mode enabled

Bits 15:0 Reserved, must be kept at reset value.

**12.3.22 SYSCFG user register 13 (SYSCFG\_UR13)**

Address offset: 0x334

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	D1SBRST
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDRS[1:0]	
														r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **D1SBRST**: D1 Standby reset

This bit indicates if a reset is generated when D1 domain enters DStandby mode.

0: A reset is generated by entering D1 Standby mode

1: D1 Standby mode is entered without reset generation

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 **SDRS[1:0]**: Secured DTCM RAM Size

This bits indicates the size of the secured DTCM RAM.

00: 2 Kbytes

01: 4 Kbytes

10: 8 Kbytes

11: 16 Kbytes

**12.3.23 SYSCFG user register 14 (SYSCFG\_UR14)**

Address offset: 0x338

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	D1STPRST
															rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **D1STPRST**: D1 Stop Reset

This bit indicates if a reset is generated when D1 domain enters in DStop mode.

0: A reset is generated entering D1 Stop mode

1: D1 Stop mode is entered without reset generation

**12.3.24 SYSCFG user register 15 (SYSCFG\_UR15)**

Address offset: 0x33C

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FZIWGDS TB
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FZIWGDSB**: Freeze independent watchdog in Standby mode

This bit indicates if the independent watchdog is frozen in Standby mode.

0: Independent Watchdog frozen in Standby mode

1: Independent Watchdog running in Standby mode

Bits 15:0 Reserved, must be kept at reset value.

### 12.3.25 SYSCFG user register 16 (SYSCFG\_UR16)

Address offset: 0x340

Reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PKP
															r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FZIWDG STP
															r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **PKP**: Private key programmed

This bit indicates if the device private key is programmed.

0: Private key not programmed

1: Private key programmed

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **FZIWDGSTP**: Freeze independent watchdog in Stop mode

This bit indicates if the independent watchdog is frozen in Stop mode.

0: Independent Watchdog frozen in Stop mode

1: Independent Watchdog running in Stop mode

### 12.3.26 SYSCFG user register 17 (SYSCFG\_UR17)

Address offset: 0x344

Reset value: 0x0000 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IO_HSLV
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **IO\_HSLV**: I/O high speed / low voltage

This bit indicates that the IOHSLV option bit is set.

0: Product is working on the full voltage range

1: Product is working below 2.5 V

12.3.27 SYSCFG register maps

The following table gives the SYSCFG register map and the reset values.

Table 85. SYSCFG register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 13 Block interconnect

### 13.1 Peripheral interconnect

#### 13.1.1 Introduction

Several peripherals have direct connections between them.

This enables autonomous communication and synchronization between peripherals, thus saving CPU resources and power consumption.

These hardware connections remove software latency, allow the design of a predictable system and result in a reduction of the number of pins and GPIOs.

#### 13.1.2 Connection overview

There are several types of connections.

- **Asynchronous connections (A)**  
The source output signal is sampled by the destination clock, leading to introduction of a possible jitter in the latency between the source output event and the destination event detection
- **Synchronous connections (S)**  
Both source and destination are synchronous (they run on the same clock), and the latency from the source to the destination is deterministic. No jitter is introduced.
- **Immediate connections (I)**  
Either the source or the destination is an analog signal.
- **Break/fault connection for TIM/HRTIM outputs (B)**  
The source output signal disables the timer outputs through a pure combinational logic path, without any latency.

- Letters in the table correspond to the type of connection described in [Section 13.1.2: Connection overview](#).
- comp1\_out and comp2\_out are connected to the inputs of an OR gate. The output of this OR gate is connected to the The lptim2\_in1\_mux3 input.

## 13.2 Wakeup from low power modes

The Extended interrupt and event controller module (EXTI) allows to wake up the system from Stop mode and/or a CPU from CStop mode. Wakeup events are coming from peripherals.

These events are handled by the EXTI either as Configurable events (**C**), or as Direct events (**D**). See *Type* column in [Table 89](#). Refer to [Section 20: Extended interrupt and event controller \(EXTI\)](#) for further details.

Three types of peripheral output signals are connected to the EXTI input events:

- The wake up signals. These signals can be generated by the peripheral without any bus interface clock, they are referred to as xxx\_wkup in [Table 89](#). Some peripherals do not have this capability.
- The interrupt signals. These signals can be generated only if the peripheral bus interface clock is running. These interrupt signals are generally directly connected to the NVIC of CPU. They are referred to as xxx\_it.
- The signals, i.e. the pulses generated by the peripheral. Once a peripheral has generated a signal, no action (flag clearing) is required at peripheral level.

Each EXTI input event has a different wakeup capability or possible target (see [Target](#) column in [Table 89](#)):

- CPU wakeup (**CPU**): the input event can be enabled to wake up the CPU
- CPU and D3 domain wakeup for autonomous Run mode (**ANY**): the input event can be enabled to wake up the CPU or the D3 domain only for an autonomous Run mode phase.

1. The source peripheral needs its bus clock in order to generate the event. This is either PCLK4 or HCLK4 in D3 domain, PCLK3 in D1 domain.
2. The source peripheral signal is not connected to the NVIC.

The Extended Interrupt and Event Controller (EXTI) module event inputs able to wake up the D3 domain for autonomous Run mode have a pending request logic that can be cleared

by 4 different input sources ([Table 90](#)). Refer to [Section 20: Extended interrupt and event controller \(EXTI\)](#) for further details.

## 13.3 DMA

In D1 domain, the MDMA allows the memory to transfer data. It can be triggered by software or by hardware, according to the connections described in [Section 13.3.1](#).

DMA Multiplexer in D2 domain (DMAMUX1) allows to map any peripheral DMA request to any stream of the DMA1 or the DMA2. In addition to this, The DMAMUX provides two other functionalities:

- It's possible to synchronize a peripheral DMA request with a timer, with an external pin or with a DMA transfer complete of another stream.
- DMA requests can be generated on a stream by the DMAMUX1 itself. This event can be triggered by a timer, by an external pin event, or by a DMA transfer complete of another stream. The number of DMA requests generated is configurable.

The connections on DMAMUX1 and DMA1/DMA2 are described in [Section 17: DMA request multiplexer \(DMAMUX\)](#), [Section 15: Direct memory access controller \(DMA1, DMA2\)](#) and [Section 16: Basic direct memory access controller \(BDMA\)](#).

DMA Multiplexer in D3 domain (DMAMUX2) has the same functionality of DMAMUX1, it is connected to the basic DMA (BDMA).

The connections on DMAMUX2 and BDMA are described in [Section 13.3.3: DMAMUX2, BDMA \(D3 domain\)](#). Refer to [Section 13.3.3: DMAMUX2, BDMA \(D3 domain\)](#) and [Section 16: Basic direct memory access controller \(BDMA\)](#) for more details.

13.3.1 MDMA (D1 domain)

## 14 MDMA controller (MDMA)

### 14.1 MDMA introduction

The master direct memory access (MDMA) is used in order to provide high-speed data transfer between memory and memory or between peripherals and memory. Data can be quickly moved by the MDMA without any CPU action. This keeps the CPU resources free for other operations.

The MDMA controller provides a master AXI interface for main memory and peripheral registers access (system access port) and a master AHB interface only for Cortex-M7 TCM memory access (TCM access port).

The MDMA works in conjunction with the standard DMA controllers (DMA1 or DMA2). It offers up to 16 channels, each dedicated to manage memory access requests from one of the DMA stream memory buffer or other peripherals (w/ integrated FIFO).

### 14.2 MDMA main features

- AXI/AHB master bus architecture, one dedicated to main memory/peripheral accesses and one dedicated to Cortex-M7 AHBS port (only for TCM accesses).
- 16 channels
- Up to 32 hardware trigger sources
- Each channel request can be selected among any of the request sources. This selection is software-configurable and allows several peripherals to initiate DMA requests. The trigger selection can be automatically changed at the end of one block transfer.
- All the channels are identical and can be connected either to a standard DMA or a peripheral request (acknowledge by data read/write) system
- Each channel also supports software trigger
- One 256-level memory buffer, split in two 128-level first-in, first-out (FIFO), that will be used to store temporary the data to be transferred (in burst or single transfer mode), for 1 or 2 consecutive buffers. The FIFO will store the data that will be transferred during the current channel block transfer (up to the block transfer size). The 2nd FIFO can be used for the next buffer to be transferred, either for the same channel or for the next channel transfer.
- The priorities between the DMA channels are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (channel 0 has priority over channel 1, etc.)
- Independent source and destination transfer width (byte, half-word, word, double-word): when the data widths of the source and destination are not equal, the MDMA can pack/unpack the necessary data to optimize the bandwidth.
- The size and address increment for both source and destination can be independently selected.

*Note: Based on this separation, some more advanced packing/unpacking operations are available at software level. As an example, 2 x 16-bit data blocks can be interleaved together using two MDMA channels, in the destination memory, by simply programming the 2 channels with an increment step of 4 bytes and a data size of 16-bit + a start address shifted by 2 between the 2 channels.*

- Incrementing, decrementing or non incrementing/fixed addressing for source and destination
- Data packing/unpacking is always done respecting the little endian convention: lower address in a data entity (double word, word or half word) contains always the lowest significant byte. This is independent of the address increment/decrement mode of both source and destination.
- Supports incremental burst transfers. The size of the burst is software-configurable, up to 128 bytes. For larger data sizes the burst length is limited, as to respect the maximum 128 bytes data burst size (e.g. 16x64-bit or 32x32-bit).
- For the TCM memory accesses, the burst access is only allowed when the increment and data size are identical and lower than or equal to 32-bit.
- 5 event flags (MDMA Channel Transfer Complete, MDMA Block Transfer complete, MDMA Block Repeat Transfer Complete, MDMA buffer transfer Complete, MDMA Transfer Error) are available and can generate interrupts.

### 14.3 MDMA functional description

#### 14.3.1 MDMA block diagram

Figure 68 shows the block diagram of the MDMA.

Figure 68. MDMA block diagram

MSv41057V3

#### 14.3.2 MDMA internal signals

Table 94 shows the internal MDMA signals.

Table 94. MDMA internal input/output signals

Signal name	Signal type	Description
mdma_hclk	Digital input	MDMA AHB clock
mdma_it	Digital output	MDMA interrupt
mdma_str[0:31]	Digital input	MDMA stream request

### 14.3.3 MDMA overview

The MDMA controller performs a direct memory transfer: as an AXI/AHB master, it can take the control of the AXI/AHB bus matrix to initiate AXI/AHB transactions.

It can carry out the following transactions:

- memory-to-memory (software triggered)
- peripheral-to-memory
- memory-to-peripheral

For the last two transaction types, the memory can also be replaced by a memory-mapped peripheral, which has no control over the MDMA flow. When these types of transaction are used and the request is coming from a standard DMA (DMA1 or DMA2), the peripheral register access is replaced by a memory access to the memory buffer used by this DMA.

*Note:* *Non-incrementing/decrementing mode will not be used for memory accesses.*

The source and destination are simply defined by the address (peripherals being memory mapped also).

The AHB slave port is used to program the MDMA controller (it supports 8/16/32-bit accesses).

The size of the data array to be transferred for a single request will be one of the following:

1. The buffer transfer size
2. The block size
3. Repeated block
4. Complete channel data (until the linked list pointer for the channel is null)

The choice of the size is done through the TRGM[1:0] (Trigger mode) selection field.

The user must choose one of them based on the data array size available (usually in the DMA1/2 memory buffer) and the “real time” requirements for other MDMA channels (knowing that a buffer transfer is the minimum data aggregate to be transferred by the MDMA without doing a new arbitration between MDMA channel requests).

For each channel, there are three key data array sizes:

1. Burst size: this is the length of the data transfer which can be performed in burst mode. This burst length defines the maximum transfer length which cannot be interrupted at bus arbitration level and can block other masters from accessing the bus)
2. Buffer transfer size: this is the length of the data array to be transferred, on a channel, before checking for MDMA requests on other channels. This is the data array transfer lengths which cannot be interrupted at MDMA level (from other channel requests).
3. Block size: this value has two meanings which can be used together:
  - a) main: this is length of the data block which is described in a block structure of the MDMA linked list (corresponds to one entry in the linked list)
  - b) selectable: when TRGM[1:0] equals 01, this is the length of the data array which is transferred on a single MDMA request activation (for the respective channel)

### 14.3.4 MDMA channel

Each of the DMA controller channel provides a unidirectional transfer link between a source and a destination.

Each channel can perform:

- Single block transfer: one block is transferred. At the end of the block, the DMA channel is disabled and an End of Channel Transfer interrupt is generated.
- Repeated block transfer: a number of blocks is transferred before disabling the channel
- Linked list transfer: when the transfer of the current data block (or last block in a repeat) is completed, a new block control structure is loaded from memory and a new block transfer is started.

The minimum amount of data to be transferred for each request (buffer size, up to 128-bytes) is programmable. The total amount of data in a block, is programmable up to 64 Kbytes. This value is decremented after each transfer. When this counter reaches 0, the end of the block is reached and an action is taken based on the repeat counter (for repeated block transfer) and/or linked list structure value.

*Note: If the block length is not a multiple of the buffer length, the last buffer transfer in the block will be shorter, covering the remaining bytes to be transferred in the current block.*

If the link structure address points to a valid memory address, the MDMA will reload the whole channel descriptor structure register contents from memory at this address. Then, a new block transfer will then be executed (on the next MDMA channel request) based on this information.

If the link structure address is 0x0, at the end of the current/repeated block transfer, the MDMA channel will be disabled and the end of channel transfer interrupt will be generated.

### 14.3.5 Source, destination and transfer modes

Both the source and destination transfers can address peripherals and memories in the entire 4-Gbyte area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The source/destination addresses can be fixed (e.g. FIFO/single data register peripherals) or incremented/decremented. The transfer can be done in single access or in burst mode (programmable).

### 14.3.6 Pointer update

The source and destination memory pointers can optionally be automatically post-incremented/decremented or kept constant after each transfer depending on the SINC[1:0] and DINC[1:0] bits in the MDMA\_CxCR register.

Disabling the increment mode is useful when the peripheral source or destination data are accessed through a single register/FIFO mode.

If the increment/decrement mode is enabled, the address of the next data transfer will be the address of the previous one incremented/decrement by 1, 2, 4 or 8 depending on the increment size programmed in the SINCOS[1:0] or DINCOS[1:0] bits in the MDMA\_CxCR register.

In order to optimize the packing operation, the increment offset size and the data size are programmable independently.

### 14.3.7 MDMA buffer transfer

This is the minimum logical amount of data (up to 128 bytes) which is transferred on an MDMA request event, on one channel.

An MDMA buffer transfer consists of a sequence of a given number of data transfers (done as single or burst data transfers). The number of data items to be transferred and their width (8-bit, 16-bit, 32-bit or 64-bit) are software programmable. The length of the burst used for data transfers is also programmable, independently.

After an event requiring a data array to be transferred, the DMA/peripheral sends a request signal to the MDMA controller. The MDMA controller serves the request depending on the channel priorities.

The request is acknowledged by writing the mask data value to the address given mask address, when these registers are set.

If the mask address register is not set (0x00 value), the request can be reset by simply reading/writing the data to the peripheral. In this case, if the request is done by a destination peripheral, the write must be set as non bufferable, in order to avoid a false new MDMA request.

The total amount of data to be transferred, on the current channel, following a MDMA request, is determined by the TRGM[1:0] field.

If TRGM[1:0] equals 00, a single buffer will be transferred, then the MDMA will wait for another request on the same channel.

*Note: In this case, the hardware request for the currently active channel (data in the FIFO) will not be considered again until the end of the write phase for this channel. In this case, even if the channel would still be active at the end of the read phase, another channel (even with lower priority) could start the read phase. Because of this, lower priority channels can be interleaved with current channel transfer.*

If TRGM[1:0] is different from 00 (multiple buffers need to be transferred), the `mdma_strx` for the current channel remains active (internally memorized) until the whole transfer defined by TRGM (block, repeated block or whole channel/linked list data) is completed. However, after transferring an individual buffer, the MDMA will enter in a new arbitration phase (between new external requests and internally memorized ones). If no other higher priority, channel request is active, a new buffer transfer will be started for the same channel.

*Note: When TRGM[1:0] is different from 00, a larger array of data will be transferred for a single request. But, as the channel arbitration is done after each buffer transfer, no higher level MDMA requests would be blocked for the more than a buffer transfer period, on any lower priority channel.*

### 14.3.8 Request arbitration

An arbiter manages the MDMA channel requests based on their priority. When MDMA is idle and after the end of each buffer transfer, all MDMA requests (hardware or software) are checked for all enabled channels.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the MDMA\_CxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: at hardware level, the channel priority is fixed. If two requests have the same software priority level, the channel with the lower number takes priority over the stream with the higher number. For example, Channel 2 takes priority over Channel 4 when they have the same software priority level.

### 14.3.9 FIFO

A FIFO structure is used to temporarily store data coming from the source before writing them to the destination. There is a central FIFO structure which is used for all channels.

In order to maximize data bandwidth and bus usage, the following mechanisms are used, allowing multiple read/write operation to be executed in parallel.

- During a buffer transfer, as soon as the FIFO contains enough data for a destination burst transfer, the write operation will start.
- When the complete data for a buffer transfer has been read into the FIFO, the arbitration procedure will be started. Following that, the next buffer data to be transferred can be read to the FIFO.

When an active channel is disabled due to an error, during a buffer transfer, the remaining data in the internal FIFO will be discarded.

### 14.3.10 Block transfer

A block is a “contiguous” array of data, up to 64 Kbytes, which is transferred by successive buffer transfers.

Each block of data is defined by the start address and the block length. When a block transfer is completed, one of the following three actions can be executed:

- The block is part of a repeated block transfer: the block length is reloaded and new block start address is computed (based on the information in the MDMA\_CxBRUR register)
- It is a single block or the last block in a repeated block transfer: the next block information is loaded from the memory (using the linked list address information, from the MDMA\_CxLAR)
- It is the last block which needs to be transferred for the current MDMA channel (MDMA\_CxLAR = 0): the channel is disabled and no further MDMA requests will be accepted for this channel

### 14.3.11 Block repeat mode

The block repeat mode allows to repeat a block transfer, with different start addresses for source and destination.

When the repeat block mode is active (repeat counter non 0), at the end of the current block transfer, the block parameters will be updated (the BNDT value reloaded and SAR/DAR values updated according to BRSUM/BRDUM configuration), and the repeat counter decremented by 1.

When the repeat block counter reaches 0, this last block will be treated as a single block transfer.

### 14.3.12 Linked list mode

The Linked list mode allows to load a new MDMA configuration (CxTCR, CxBNDTR, CxSAR, CxDAR, CxBRUR, CxLAR, CxTBR, CxMAR and CxMDR registers), from the address given in the CxLAR register. This address must address a memory mapped on the AXI system bus.

Following this operation, the channel is ready to accept new requests, as defined in the block/repeated block modes above, or continue the transfer if TRGM[1:0] equals 11.

The trigger source can be automatically changed, when loading the CxTBR value.

The TRGM and SWRM values must not be changed when TRGM[1:0] equals 11.

### 14.3.13 MDMA transfer completion

Different events can generate an end of transfer by setting the CTCIFx bit in the status register (MDMA\_CxISR):

- The MDMA\_CxBNDTR counter has reached zero, the Block Repeat Counter is 0 and the Link list pointer address is 0
- The channel is disabled before the end of transfer (by clearing the EN bit in the MDMA\_CxCR register) and all the remaining data have been transferred from the FIFO to the destination

### 14.3.14 MDMA transfer suspension

At any time, a MDMA transfer can be suspended in order to be restarted later on or to be definitively disabled before the end of the MDMA transfer.

There are two cases:

- The channel is disabled, with no later-on restart from the point where it was stopped. There is no particular action to do, besides clearing the EN bit in the MDMA\_CxCR register to disable the channel. The stream can take time to be disabled (on going buffer transfer is completed first). The transfer complete interrupt flag is set in order to indicate the end of transfer. The value of the EN bit in MDMA\_CxCR is now 0 to confirm the channel interruption. The MDMA\_CxNDTR register contains the number of remaining data items at the moment when the channel was stopped so that the software can determine how many data items have been transferred before the channel was interrupted.
- The channel is suspended before the number of remaining bytes to be transferred in the MDMA\_CxBNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the channel. The channel transfer complete interrupt flag CTCIF is set in order to indicate the end of transfer. If the MDMA\_CxBNDTR, SAR and DAR registers are not modified by software, the transfer will continue when the channel is re-enabled. CTCIF must also be reset before restarting the channel.

*Note:* If the completed buffer is the last of the block, the configuration registers are also updated before disabling the channel, in order to be correctly prepared for a soft restart.

*Note:* Before reprogramming the channel, software must wait the CTCIF register is set, in order to guarantee that any ongoing operation has been completed.

### 14.3.15 Error management

The MDMA controller can detect the following errors:

The transfer error interrupt flag (TEIFx) is set when:

- A bus error occurs during a MDMA read or a write access
- The address alignment does not correspond to the data size
- The block size is not a multiple of the data size (for source and/or destination): this error is activated on the last transfer and the error address points to the last transfer (which cannot be done)

## 14.4 MDMA interrupts

For each MDMA channel, an interrupt can be produced on the following events:

- Channel Transfer Completed
- Block-Transfer Completed
- Block-Transfer Repeat Completed
- buffer Transfer Completed
- Transfer Error

Separate interrupt enable control bits are available for flexibility as shown in [Table 95](#).

Table 95. MDMA interrupt requests

Interrupt event	Event flag	Enable control bit
Channel Transfer Completed	CTCIF	CTCIE
Block-Transfer Repeat completed	BTRIF	BTRIE
Block-Transfer completed	BTIF	BTIE
buffer Transfer Completed	TCIF	TCIE
Transfer Error	TEIF	TEIE

Note: Before setting an Enable control bit to 1, the corresponding event flag should be cleared, otherwise an interrupt might be immediately generated, if the bit is already set.

Note: When at least one interrupt flag and the respective enable control bit are set, the channel interrupt bit is set in the GISR . The Interrupt output is also activated. This will generate an interrupt if the respective interrupt channel is enabled in the NVIC.

## 14.5 MDMA registers

The MDMA registers can be accessed in word/half-word or byte format.

### 14.5.1 MDMA Global Interrupt/Status Register (MDMA\_GISR0)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GIF15	GIF14	GIF13	GIF12	GIF11	GIF10	GIF9	GIF8	GIF7	GIF6	GIF5	GIF4	GIF3	GIF2	GIF1	GIF0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, read as 0, for all unused channels.

Bits 15:0 **GIFx**: Channel x global interrupt flag (x=0..15)

This bit is set and reset by hardware. It is a logical OR of all the Channel x interrupt flags (CTCIFx, BTIFx, BRTIFx, TEIFx) which are enabled in the interrupt mask register (CTCIEx, BTIEx, BRTIEx, TEIEx)

0: No interrupt generated by channel x

1: Interrupt generated by channel x

### 14.5.2 MDMA channel x interrupt/status register (MDMA\_CxISR) (x = 0..15)

Address offset: 0x40 + 0x40 × *channel number*

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRQAx
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TCIFx	BTIFx	BRTIFx	CTCIFx	TEIFx
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16 CRQAx:** Channel x ReQuest Active flag

This bit is set by software writing 1 to the SWRQx bit in the MDMA\_CxCR register, in order to request a MDMA transfer, and the channel x is enabled.

It is also set by hardware when the channel request become active and the channel is enabled. The hardware request memorized until it is served.

It is cleared by hardware, when the Channel x Request is completed (after the source write phase of the last buffer transfer due for the current request).

0: The MDMA transfer mdma\_strx is inactive for channel x.

1: The MDMA transfer mdma\_strx is active for channel x

This bit is also reset by hardware when the channel is disabled (in case of transfer error or when reaching the end of the channel data transfer - repeat block = 0 and linked list pointer null - or by software programming the channel enable bit to 0 before that).

Bits 15:5 Reserved, must be kept at reset value.

**Bit 4 TCIFx:** Channel x buffer transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the MDMA\_IFCRy register.

0: No buffer transfer complete event on channel x

1: A buffer transfer complete event occurred on channel x

TC is set when a single buffer was transferred. It will be activated on each channel transfer request.

This can be used as a debug feature (without interrupt), indicating that (at least) an MDMA buffer transfer had been generated since the last flag reset.

**Bit 3 BTIFx:** Channel x block transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the MDMA\_IFCRy register.

0: No block transfer complete event on channel x

1: A block transfer complete event occurred on channel x

**Bit 2 BRTIFx:** Channel x block repeat transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the MDMA\_IFCRy register.

0: No block repeat transfer complete event on channel x

1: A block repeat transfer complete event occurred on channel x

Bit 1 **CTCIFx**: Channel x Channel Transfer Complete interrupt flag  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the MDMA\_IFCRy register.  
 0: No channel transfer complete event on channel x  
 1: A channel transfer complete event occurred on channel x  
 CTC is set when the last block was transferred and the channel has been automatically disabled.  
 CTC is also set when the channel is suspended, as a result of writing EN bit to 0.

Bit 0 **TEIFx**: Channel x transfer error interrupt flag  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the MDMA\_IFCRy register.  
 0: No transfer error on stream x  
 1: A transfer error occurred on stream x

**14.5.3 MDMA channel x interrupt flag clear register (MDMA\_CxIFCR) (x = 0..15)**

Address offset: 0x44 + 0x40 × channel number

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLTCIFx	CBTIFx	CBRTIFx	CCTCIFx	CTEIFx
r	r	r	r	r	r	r	r	r	r	r	w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

- Bit 4 **CLTCIFx**: Clear buffer Transfer Complete Interrupt Flag for channel x  
 Writing 1 into this bit clears TCIFx in the MDMA\_ISRy register
- Bit 3 **CBTIFx**: Channel x Clear block transfer complete interrupt flag  
 Writing 1 into this bit clears BTIFx in the MDMA\_ISRy register
- Bit 2 **CBRTIFx**: Channel x clear block repeat transfer complete interrupt flag  
 Writing 1 into this bit clears BRTIFx in the MDMA\_ISRy register
- Bit 1 **CCTCIFx**: Clear Channel transfer complete interrupt flag for channel x  
 Writing 1 into this bit clears CTCIFx in the MDMA\_ISRy register
- Bit 0 **CTEIFx**: Channel x clear transfer error interrupt flag  
 Writing 1 into this bit clears TEIFx in the MDMA\_ISRy register

### 14.5.4 MDMA Channel x error status register (MDMA\_CxESR) (x = 0..15)

Address offset: 0x48 + 0x40 × channel number

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	BSE	ASE	TEMD	TELD	TED	TEA[6:0]						
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

**Bit 11 BSE:** Block Size Error

These bit is set by hardware, when the block size is not an integer multiple of the data size either for source or destination. TED will indicate whether the problem is on the source or destination.

It is cleared by software writing 1 to the **CTEIFx** bit in the MDMA\_IFCRy register.

0: No block size error.

1: Programmed block size is not an integer multiple of the data size.

**Bit 10 ASR:** Address/Size Error

These bit is set by hardware, when the programmed address is not aligned with the data size. TED will indicate whether the problem is on the source or destination.

It is cleared by software writing 1 to the **CTEIFx** bit in the MDMA\_IFCRy register.

0: No address/size error.

1: Programmed address is not coherent with the data size.

**Bit 9 TEMD:** Transfer Error Mask Data

These bit is set by hardware, in case of a transfer error while writing the Mask Data.

It is cleared by software writing 1 to the **CTEIFx** bit in the MDMA\_IFCRy register.

0: No mask write access error.

1: The last transfer error on the channel was a related to a write of the Mask Data.

**Bit 8 TELD:** Transfer Error Link Data

These bit is set by hardware, in case of a transfer error while reading the block link data structure.

It is cleared by software writing 1 to the **CTEIFx** bit in the MDMA\_IFCRy register.

0: No link data read access error.

1: The last transfer error on the channel was a related to a read of the Link Data structure.

**Bit 7 TED:** Transfer Error Direction

These bit is set and cleared by hardware, in case of an MDMA data transfer error.

0: The last transfer error on the channel was a related to a read access.

1: The last transfer error on the channel was a related to a write access.

Bits 6:0 **TEA[6:0]**: Transfer Error Address

These bits are set and cleared by hardware, in case of an MDMA data transfer error. It is used in conjunction with TED.

This field indicates the 7 LSBits of the address which generated a transfer/access error.

It can be used by software to retrieve the failing address, by adding this value (truncated to the buffer transfer length size) to the current SAR/DAR value.

*Note: The SAR/DAR current value doesn't reflect this last address due to the FIFO management system. The SAR/DAR are only updated at the end of a (buffer) transfer (of TLEN+1 bytes).*

*Note: It is not set in case of a link data error.*

### 14.5.5 MDMA channel x control register (MDMA\_CxCR) (x = 0..15)

This register is used to control the concerned channel.

Address offset:  $0x4C + 0x40 \times \text{channel number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWRQ
															w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	WEX	HEX	BEX	Res.	Res.	Res.	Res.	PL[1:0]		TCIE	BTIE	BRTIE	CTCIE	TEIE	EN
	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SWRQ**: Software Request

Writing 1 into this bit sets the CRQAx in MDMA\_ISRy register, activating the request on Channel x

*Note: Either the whole CxCR register or the 8-bit/16-bit register at Address offset:  $0x4E + 0x40 \times \text{channel number}$  can be used for SWRQ activation.*

*In case of a software request, acknowledge is not generated (neither hardware signal, nor CxMAR write access).*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WEX**: Word Endianess exchange

This bit is set and cleared by software.

0: Little endianess preserved for words

1: word order exchanged in double word

When this bit is set, the word order in the destination double word is reversed: higher address word contains the data read from the lower address of the source.

If destination is not a double word, do not care of the value of this bit.

This bit is protected and can be written only if EN is 0.

Bit 13 **HEX**: Half word Endianess exchange

This bit is set and cleared by software.

0: Little endianess preserved for half words

1: half-word order exchanged in each word

When this bit is set, the half-word order in each destination word is reversed: higher address half-word contains the data read from the lower address of the source.

If destination length is shorter than word, do not care of the value of this bit.

This bit is protected and can be written only if EN is 0.

Bit 12 **BEX**: Byte Endianess exchange

This bit is set and cleared by software.

0: Little endianess preserved for bytes

1: byte order exchanged in each half-word

When this bit is set, the byte order in each destination Half Word is reversed: higher address word contains the data read from the lower address of the source.

If destination is byte, do not care of the value of this bit.

This bit is protected and can be written only if EN is 0.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

- Bits 7:6 **PL[1:0]**: Priority level  
 These bits are set and cleared by software.  
 00: Low  
 01: Medium  
 10: High  
 11: Very high  
 These bits are protected and can be written only if EN is 0.
- Bit 5 **TCIE**: buffer Transfer Complete interrupt enable  
 This bit is set and cleared by software.  
 0: TC interrupt disabled  
 1: TC interrupt enabled
- Bit 4 **BTIE**: Block Transfer interrupt enable  
 This bit is set and cleared by software.  
 0: BT complete interrupt disabled  
 1: BT complete interrupt enabled
- Bit 3 **BRTIE**: Block Repeat transfer interrupt enable  
 This bit is set and cleared by software.  
 0: BT interrupt disabled  
 1: BT interrupt enabled
- Bit 2 **CTCIE**: Channel Transfer Complete interrupt enable  
 This bit is set and cleared by software.  
 0: TC interrupt disabled  
 1: TC interrupt enabled
- Bit 1 **TEIE**: Transfer error interrupt enable  
 This bit is set and cleared by software.  
 0: TE interrupt disabled  
 1: TE interrupt enabled
- Bit 0 **EN**: Channel enable / flag channel ready when read low  
 This bit is set and cleared by software.  
 0: Channel disabled  
 1: Channel enabled  
 This bit can be cleared by hardware:
  - on a MDMA end of transfer (stream ready to be configured)
  - if a transfer error occurs on the AHB/AXI master buses (bus error/hard fault)
  - if another error condition is encountered (data alignment, block/data size incompatibility)
 When this bit is reset by software, the ongoing buffer transfer (if any) will be completed. All status/configuration registers will keep their current values. If the channel is re enabled without writing these registers, the channel will continue from the point where it was interrupted.  
 When this bit is read as 0, the software is allowed to program the configuration registers. It is forbidden to write these registers when the EN bit is read as 1 (writes are ignored).  
*Note: When this bit is reset by software, it is recommended to wait for the CTCIF = 1, in order to ensure that any ongoing buffer transfer has been completed, before reprogramming the channel.*

### 14.5.6 MDMA channel x Transfer Configuration register (MDMA\_CxTCR) (x = 0..15)

This register is used to configure the concerned channel.

Address offset: 0x50 + 0x40 × channel number

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWM	SWRM	TRGM[1:0]		PAM[1:0]		PKE	TLEN[6:0]						DBURST[2:1]		
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBURST [0]	SBURST[2:0]			DINCOS[1:0]		SINCOS[1:0]		DSIZE[1:0]		SSIZE[1:0]		DINC[1:0]		SINC[1:0]	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

**Bit 31 BWM:** Bufferable Write Mode

This bit is set and cleared by software.

0: The destination write operation is non-bufferable.

1: The destination write operation is bufferable.

This bit is protected and can be written only if EN is 0.

*Note: All MDMA destination accesses are non-cacheable.*

**Bit 30 SWRM:** Software Request Mode

This bit is set and cleared by software. If a hardware or software request is currently active, the bit change will be delayed until the current transfer is completed.

0: hardware request are taken into account: the transfer is initiated as defined by TRGM value and acknowledged by the MDMA ACKx signal.

If the CxMAR contains a valid address, the CxMDR value will also be written at CxMAR address.

1: hardware request are ignored. Transfer is triggered by software writing 1 to the SWRQ bit.

This bit is protected and can be written only if EN is 0.

**Bits 29:28 TRGM[1:0]:** Trigger Mode

These bits are set and cleared by software.

00: Each MDMA request (software or hardware) triggers a buffer transfer

01: Each MDMA request (software or hardware) triggers a block transfer

10: Each MDMA request (software or hardware) triggers a repeated block transfer (if the block repeat is 0, a single block is transferred)

11: Each MDMA request (software or hardware) triggers the transfer of the whole data for the respective channel (e.g. linked list) until the channel reach the end and it is disabled.

*Note: If TRGM is 11 for the current block, all the values loaded at the end of the current block through the linked list mechanism must keep the same value (TRGM=11) and the same SWRM value, otherwise the result is undefined.*

These bits are protected and can be written only if EN is 0.

Bits 27:26 **PAM[1:0]**: Padding/Alignement Mode

These bits are set and cleared by software.

Case 1: Source data size smaller than destination data size - 3 options are valid.

00: Right Aligned, padded w/ 0s (default)

01: Right Aligned, Sign extended

10: Left Aligned (padded with 0s)

11: Reserved

Case 2: Source data size larger than destination data size.

00: Right Aligned - only the LSBs part of the Source is written to the destination address

10: Left Aligned - only the MSBs part of the Source is written to the destination address

The remainder part is discarded.

When PKE = 1 or DSIZE=SSIZE, these bits are ignored.

These bits are protected and can be written only if EN is 0

Bit 25 **PKE**: Pack Enable

This bit is set and cleared by software.

0: The source data is written to the destination as is.

If the Source Size is smaller than the destination, it will be padded according to the PAM value.

If the Source data size is larger than the destination one, it will be truncated. The alignment will be done according to the PAM[1:0] value.

1: The source data is packed/unpacked into the destination data size. All data are right aligned, in Little Endian mode.

This bit is protected and can be written only if EN is 0

Bits 24:18 **TLEN[6:0]**: buffer Transfer Length (number of bytes - 1)

These bits are set and cleared by software.

The value of TLEN+1 represents the number of bytes to be transferred in a single transfer.

The Transfer Length MUST be a multiple of the data size (for both Source and Destination)

*Note: When the source/destination sizes are different and padding/truncation is used, the TLEN+1 refers to the source data array size.*

These bits are protected and can be written only if EN is 0

DBURST value must be programmed in order to ensure that the burst size will be lower than the Transfer Size.

Bits 17:15 **DBURST[2:0]**: Destination burst transfer configuration

These bits are set and cleared by software.

000: single transfer

N: burst of  $2^N$  beats

These bits are protected and can be written only if EN is 0

DBURST value must be programmed as to ensure that the burst size will be lower than the Transfer Length. If this is not ensured, the result is unpredictable.

*Note: When the destination bus is TCM/AHB (DBUS=1) and DINCOS=11 or DINC=00 or DINCOS/=DSIZE, DBURST must be programmed to 000 (single transfer), else the result is unpredictable.*

*Note: When the destination bus is system/AXI bus (DBUS=0) and DINC=00, DBURST must be maximum 100 (burst of 16), else the result is unpredictable.*

Bits 14:12 **SBURST[2:0]**: Source burst transfer configuration

These bits are set and cleared by software.

000: single transfer

N: burst of  $2^N$  beats

These bits are protected and can be written only if EN is 0

SBURST value must be programmed as to ensure that the burst size will be lower than the transfer length. If this is not ensured, the result is unpredictable.

*Note: When the source bus is TCM (SBUS=1) and SINCOS=11 or SINC = 00 or SINCOS/=SSIZE, SBURST must be programmed to 000 (single transfer), else the result is unpredictable.*

*Note: When the source bus is system/AXI bus (SBUS=0) and SINC=00, SBURST must be maximum 100 (burst of 16), else the result is unpredictable.*

Bits 11:10 **DINCOS[1:0]**: Destination increment offset size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

This bits have no meaning if bit DINC[1:0] = '00'.

These bits are protected and can be written only if EN = '0'.

If DINCOS < DSIZE and DINC != 00, the result will be unpredictable.

If destination is AHB and DBURST != 000, destination address must be aligned with DINCOS size, else the result is unpredictable.

Bits 9:8 **SINCOS[1:0]**: Source increment offset size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

This bits have no meaning if bit SINC[1:0] = '00'.

These bits are protected and can be written only if EN = '0'.

If SINCOS < SSIZE and SINC != 00, the result will be unpredictable.

If source is TCM/AHB and SBURST != 000, source address must be aligned with SINCOS size, else the result is unpredictable.

Bits 7:6 **DSIZE[1:0]**: Destination data size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

These bits are protected and can be written only if EN is 0.

*Note: If a value of 11 is programmed for the TCM access/AHB port, a transfer error will occur (TEIF bit set)*

*If DINCOS < DSIZE and DINC != 00, the result will be unpredictable.*

*Note: DSIZE = 11 (double-word) is forbidden when destination is TCM/AHB bus (DBUS=1).*

Bits 5:4 **SSIZE[1:0]**: Source data size

These bits are set and cleared by software.

- 00: Byte (8-bit)
- 01: Half-word (16-bit)
- 10: Word (32-bit)
- 11: Double-Word (64-bit)

These bits are protected and can be written only if EN is 0

*Note: If a value of 11 is programmed for the TCM access/AHB port, a transfer error will occur (TEIF bit set)*

*If SINCOS < SSIZE and SINC != 00, the result will be unpredictable.*

*Note: SSIZE = 11 (double-word) is forbidden when source is TCM/AHB bus (SBUS=1).*

Bits 3:2 **DINC[1:0]**: Destination increment mode

These bits are set and cleared by software.

- 00: Destination address pointer is fixed
- 10: Destination address pointer is incremented after each data transfer (increment is done according to DINCOS)
- 11: Destination address pointer is decremented after each data transfer (increment is done according to DINCOS)

These bits are protected and can be written only if EN is 0

*Note: When destination is AHB (DBUS=1), DINC = 00 is forbidden.*

Bits 1:0 **SINC[1:0]**: Source increment mode

These bits are set and cleared by software.

- 00: Source address pointer is fixed
- 10: Source address pointer is incremented after each data transfer (increment is done according to SINCOS)
- 11: Source address pointer is decremented after each data transfer (decrement is done according to SINCOS)

These bits are protected and can be written only if EN is 0

*Note: When source is AHB (SBUS=1), SINC = 00 is forbidden.*

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x00).

### 14.5.7 MDMA Channel x block number of data register (MDMA\_CxBNDTR) (x = 0..15)

Address offset: 0x54 + 0x40 × channel number

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRC[11:0]												BRDUM	BRSUM	Res.	BNDT[16]
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:20 **BRC[11:0]**: Block Repeat Count

This field contains the number of repetitions of the current block (0 to 4095). When the channel is enabled, this register is read-only, indicating the remaining number of blocks, excluding the current one. This register decrements after each complete block transfer. Once the last block transfer has completed, this register can either stay at zero or be reloaded automatically from memory (in Linked List mode - i.e. Link Address valid). These bits are protected and can be written only if EN is 0.

Bit 19 **BRDUM**: Block Repeat Destination address Update Mode

0: At the end of a Block transfer, the DAR register will be updated by adding the DUV to the current DAR value (current Destination Address)

1: At the end of a block transfer, the DAR register will be updated by subtracting the DUV from the current DAR value (current Destination Address)

These bits are protected and can be written only if EN is 0.

Bit 18 **BRSUM**: Block Repeat Source address Update Mode

0: At the end of a block transfer, the SAR register will be updated by adding the SUV to the current SAR value (current Source Address)

1: At the end of a block transfer, the SAR register will be updated by subtracting the SUV from the current SAR value (current Source Address)

These bits are protected and can be written only if EN is 0.

Bit 17 Reserved, must be kept at reset value.

Bits 16:0 **BNDT[16:0]**: Block Number of data bytes to transfer

Number of bytes to be transferred (0 up to 65536) in the current block. When the channel is enabled, this register is read-only, indicating the remaining data items to be transmitted. During the channel activity, this register decrements, indicating the number of data items remaining in the current block.

Once the block transfer has completed, this register can either stay at zero or be reloaded automatically with the previously programmed value if the channel is configured in block Repeat mode.

If the value of this register is zero, no transaction can be served even if the stream is enabled.

These bits are protected and can be written only if EN is 0.

*Note: 1: If the BNDT value is not an integer multiple of the TLEN+1 value, the last transfer will be shorter and contain only the remaining data in the Block.*

*Note: 2: The size of the block must be a multiple of the source and destination data size. If this is not true, an error will be set and the no data will be written.*

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x04)

### 14.5.8 MDMA channel x source address register (MDMA\_CxSAR) (x = 0..15)

Address offset:  $0x58 + 0x40 \times \text{channel number}$

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SAR[31:16]																
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SAR[15:0]																
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SAR[31:0]**: Source address

These bits represent the base address of the peripheral data register from/to which the data will be read. They must be aligned with the SSIZE (e.g. SAR[1:0] = 00 when SSIZE=10), but may be unaligned with the SINCOS.

When source is TCM/AHB, if address is not aligned with SINCOS, access must be programmed as single (SBURST=000).

These bits are write-protected and can be written only when bit EN = '0' in the DMA\_SxCR register. During the channel activity, this register is updated, reflecting the current address from which the data will be read next.

When the block repeat mode is active, when a block transfer is completed, the source address is updated by adding/subtracting the SAU value to the current value (already updated after the last transfer in the block).

When the Linked List mode is active, at the end of a block (repeated or not) transfer, the SAR value will be loaded from memory (from address LSA + m)

In Linked List mode, at the end of a Block (single or last Block in repeated Block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x08)

### 14.5.9 MDMA channel x destination address register (MDMA\_CxDAR) (x = 0..15)

Address offset:  $0x5C + 0x40 \times \text{channel number}$

Reset value: 0x0000 0000.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DAR[31:16]																
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAR[15:0]																
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DAR[31:0]**: Destination address

Base address of the destination address to which the data will be written.

These bits are write-protected and can be written only when bit EN = '0' in the DMA\_SxCR register. Must be aligned with the DSIZE (e.g. DAR[0] = 0 when DSIZE=01), but may be unaligned with the DINCOS.

When destination is AHB, if address is not aligned with DINCOS, access must be programmed as single (DBURST=000).

During the channel activity, this register is updated, reflecting the current address to which the data will be written next.

When the block repeat mode is active, when a block transfer is completed, the Destination address is updated by adding/subtracting the DAU value to the current value (after the last transfer in the block).

When the Linked List mode is active, at the end of a block (repeated or not) transfer, the DAR value will be loaded from memory (from address LSA + m)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x0C)

**14.5.10 MDMA channel x Block Repeat address Update register  
MDMA\_CxBRUR (x = 0..15)**

Address offset: 0x60 + 0x40 × channel number

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DUV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **DUV[15:0]**: Destination address Update Value

This value is used to update (by addition or subtraction) the current destination address at the end of a block transfer. Must be an integer multiple of DSIZE, in order to keep DAR aligned to DSIZE (e.g. DAR[1:0] = 00 when DSIZE=10).

If this value is 0, the next repetition of the block transfer will continue to the next address.

When the block repeat mode is not active (BRC=0), this field is ignored.

These bits are write-protected and can be written only when bit EN = '0' in the MDMA\_CxCR register.

*Note: This field must be programmed to 0 when DINC[1:0] = 00.*

Bits 15:0 **SUV[15:0]**: Source address Update Value

This value is used to update (by addition or subtraction) the current source address at the end of a block Transfer. Must be an integer multiple of SSIZE, in order to keep SAR aligned to SSIZE (e.g. SAR[1:0] = 00 when SSIZE=10).

If this value is 0, the next repetition of the block transfer will continue from the next address.

When the block repeat mode is not active (BRC=0), this field is ignored.

These bits are write-protected and can be written only when bit EN = '0' in the MDMA\_CxCR register.

*Note: This field must be programmed to 0 when SINC[1:0] = 00.*

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x10)

**14.5.11 MDMA channel x Link Address register (MDMA\_CxLAR)  
(x = 0..15)**

Address offset: 0x64 + 0x40 × channel number

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LAR[31:16]																
	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LAR[15:0]																
	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	r	r	r	

Bits 31:0 **LAR[31:0]**: Link Address Register

At the end of a (repeated) block Transfer, the current channel configuration registers (CxTCR, CxBNDTR, CxSAR, CxDAR, CxBRUR, CxMAR, CxMDR and the CxLAR register itself) are loaded with the data structure found at this address.

If the value of this register is 0, no register update will take place, the channel will be disabled and the CTCIF will be set, indicating the end of the transfer for this channel. These bits are write-protected and can be written only when bit EN = '0' in the MDMA\_CxCR register.

The channel configuration (LAR address) must be in the AXI address space.

LAR value must be aligned at a Double Word address, i.e. LAR[2:0] = 0x0

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x14).

*Note: The new value is only taken into account after all registers are updated, for the next end of block.*

**14.5.12 MDMA channel x Trigger and Bus selection Register (MDMA\_CxTBR) (x = 0..15)**

Address offset: 0x68 + 0x40 × channel number

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBUS	SBUS
														rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TSEL[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DBUS**: Destination BUS select

- 0: The system/AXI bus is used as destination (write operation) on channel x.
  - 1: The AHB bus/TCM is used as destination (write operation) on channel x.
- This bit is protected and can be written only if EN is 0.

Bit 16 **SBUS**: Source BUS select

- 0: The system/AXI bus is used as source (read operation) on channel x.
  - 1: The AHB bus/TCM is used as source (read operation) on channel x.
- This bit is protected and can be written only if EN is 0.

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **TSEL[5:0]**: Trigger Selection

This bit field selects the hardware trigger (RQ) input for channel x. The ACK is sent on the ACK output having the same index value.

When SWRM bit is set (software request selected), this bit field is ignored.

These bits are write-protected and can be written only when bit EN = '0' in the MDMA\_CxCR register.

*Note: If multiple channels are triggered by the same event (have the same TSEL value), all of them will be triggered in parallel. However, only the channel with the lowest index will acknowledge the request.*

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x18)

**14.5.13 MDMA channel x Mask address register (MDMA\_CxMAR) (x = 0..15)**

Address offset:  $0x70 + 0x40 \times \text{channel number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MAR[31:0]**: Mask address

A write of the MDR value will also be done to this address. This allows to clear the RQ signal generated by the DMA2 by writing to its Interrupt Clear register.

If the value of this register is 0, this function is disabled. These bits are write-protected and can be written only when bit EN = '0' in the MDMA\_CxCR register.

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x20)

**14.5.14 MDMA channel x Mask Data register (MDMA\_CxMDR) (x = 0..15)**

Address offset:  $0x74 + 0x40 \times \text{channel number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MDR[31:0]**: Mask Data

A write of the MDR value will also be done to the address defined by the MAR register. This allows to clear the RQ signal generated by the DMA2 by writing to its Interrupt Clear register.

These bits are write-protected and can be written only when bit EN = '0' in the MDMA\_CxCR register.

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x24)

### 14.5.15 MDMA register map

Table 96 summarizes the MDMA registers.

**Table 96. MDMA register map and reset values**

Offset	Register name reset value	Register size																																
		31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 15 Direct memory access controller (DMA1, DMA2)

### 15.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory and between memory and memory. Data can be quickly moved by DMA without any CPU action. This keeps CPU resources free for other operations.

The DMA controller combines a powerful dual AHB master bus architecture with independent FIFO to optimize the bandwidth of the system, based on a complex bus matrix architecture.

The two DMA controllers have 16 streams in total (8 for each controller), each dedicated to managing memory access requests from one or more peripherals. Each stream can have up to 8 channels (requests) in total. And each has an arbiter for handling the priority between DMA requests.

### 15.2 DMA main features

The main DMA features are:

- Dual AHB master bus architecture, one dedicated to memory accesses and one dedicated to peripheral accesses
- AHB slave programming interface supporting only 32-bit accesses
- 8 streams for each DMA controller, up to 115 channels (requests) per stream
- Four-word depth 32 first-in, first-out memory buffers (FIFOs) per stream, that can be used in FIFO mode or direct mode:
  - FIFO mode: with threshold level software selectable between 1/4, 1/2 or 3/4 of the FIFO size
  - Direct modeEach DMA request immediately initiates a transfer from/to the memory. When it is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads only one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.
- Each stream can be configured by hardware to be:
  - a regular channel that supports peripheral-to-memory, memory-to-peripheral and memory-to-memory transfers
  - a double buffer channel that also supports double buffering on the memory side
- Each of the 8 streams are connected to dedicated hardware DMA channels (requests)
- Priorities between DMA stream requests are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (request 0 has priority over request 1, etc.)

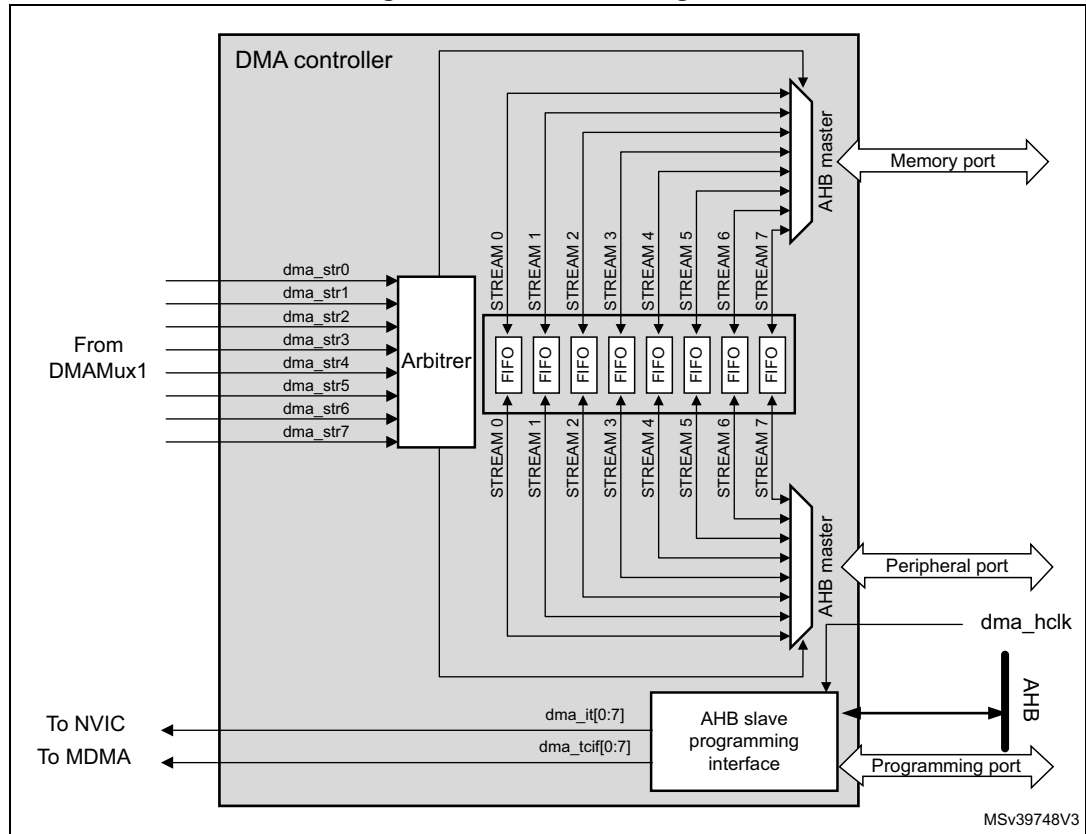

- Each stream also supports software trigger for memory-to-memory transfers
- Each stream request can be selected via DMAMux1 among up to 115 possible channel requests. This selection is software-configurable and allows a great number of peripherals to initiate DMA requests
- The number of data items to be transferred can be managed either by the DMA controller or by the peripheral:
  - DMA flow controller: the number of data items to be transferred is software-programmable from 1 to 65535
  - Peripheral flow controller: the number of data items to be transferred is unknown and controlled by the source or the destination peripheral that signals the end of the transfer by hardware
- Independent source and destination transfer width (byte, half-word, word): when the data widths of the source and destination are not equal, the DMA automatically packs/unpacks the necessary transfers to optimize the bandwidth. This feature is only available in FIFO mode
- Incrementing or non-incrementing addressing for source and destination
- Supports incremental burst transfers of 4, 8 or 16 beats. The size of the burst is software-configurable, usually equal to half the FIFO size of the peripheral
- Each stream supports circular buffer management
- 5 event flags (DMA Half Transfer, DMA Transfer complete, DMA Transfer Error, DMA FIFO Error, Direct Mode Error) logically ORed together in a single interrupt request for each stream

### 15.3 DMA functional description

#### 15.3.1 DMA block diagram

Figure 69 shows the block diagram of a DMA.

Figure 69. DMA block diagram

#### 15.3.2 DMA internal signals

Table 97 shows the internal DMA signals.

Table 97. DMA internal input/output signals

Signal name	Signal type	Description
dma_hclk	Digital input	DMA AHB clock
dma_it[0:7]	Digital outputs	DMA stream [0:7] global interrupts
dma_tcif[0:7]	Digital outputs	MDMA triggers
dma_str[0:7]	Digital input	DMA stream [0:7] requests

### 15.3.3 DMA overview

The DMA controller performs direct memory transfer: as an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

It can carry out the following transactions:

- peripheral-to-memory
- memory-to-peripheral
- memory-to-memory

The DMA controller provides two AHB master ports: the *AHB memory port*, intended to be connected to memories and the *AHB peripheral port*, intended to be connected to peripherals. However, to allow memory-to-memory transfers, the *AHB peripheral port* must also have access to the memories.

The AHB slave port is used to program the DMA controller (it supports only 32-bit accesses).

### 15.3.4 DMA transactions

A DMA transaction consists of a sequence of a given number of data transfers. The number of data items to be transferred and their width (8-bit, 16-bit or 32-bit) are software-programmable.

Each DMA transfer consists of three operations:

- A loading from the peripheral data register or a location in memory, addressed through the DMA\_SxPAR or DMA\_SxM0AR register
- A storage of the data loaded to the peripheral data register or a location in memory addressed through the DMA\_SxPAR or DMA\_SxM0AR register
- A post-decrement of the DMA\_SxNDTR register, which contains the number of transactions that still have to be performed

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an Acknowledge signal is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the Acknowledge signal from the DMA controller. Once the request has been deasserted by the peripheral, the DMA controller releases the Acknowledge signal. If there are more requests, the peripheral can initiate the next transaction.

### 15.3.5 DMA request mapping

The DMA request mapping to peripherals and DMA channels is described in [Section 17.3.2: DMAMUX1 mapping](#).

### 15.3.6 Arbiter

An arbiter manages the 8 DMA stream requests based on their priority for each of the two AHB master ports (memory and peripheral ports) and launches the peripheral/memory access sequences.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the DMA\_SxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: If two requests have the same software priority level, the stream with the lower number takes priority over the stream with the higher number. For example, Stream 2 takes priority over Stream 4.

### 15.3.7 DMA streams

Each of the 8 DMA controller streams provides a unidirectional transfer link between a source and a destination.

Each stream can be configured to perform:

- Regular type transactions: memory-to-peripherals, peripherals-to-memory or memory-to-memory transfers
- Double-buffer type transactions: double buffer transfers using two memory pointers for the memory (while the DMA is reading/writing from/to a buffer, the application can write/read to/from the other buffer).

The amount of data to be transferred (up to 65535) is programmable and related to the source width of the peripheral that requests the DMA transfer connected to the peripheral AHB port. The register that contains the amount of data items to be transferred is decremented after each transaction.

### 15.3.8 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4 GB area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The direction is configured using the DIR[1:0] bits in the DMA\_SxCR register and offers three possibilities: memory-to-peripheral, peripheral-to-memory or memory-to-memory transfers. [Table 98](#) describes the corresponding source and destination addresses.

**Table 98. Source and destination address**

Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
00	Peripheral-to-memory	DMA_SxPAR	DMA_SxM0AR
01	Memory-to-peripheral	DMA_SxM0AR	DMA_SxPAR
10	Memory-to-memory	DMA_SxPAR	DMA_SxM0AR
11	Reserved	-	-

When the data width (programmed in the PSIZE or MSIZE bits in the DMA\_SxCR register) is a half-word or a word, respectively, the peripheral or memory address written into the DMA\_SxPAR or DMA\_SxM0AR/M1AR registers has to be aligned on a word or half-word address boundary, respectively.

**Peripheral-to-memory mode**

Figure 70 describes this mode.

When this mode is enabled (by setting the bit EN in the DMA\_SxCR register), each time a peripheral request occurs, the stream initiates a transfer from the source to fill the FIFO.

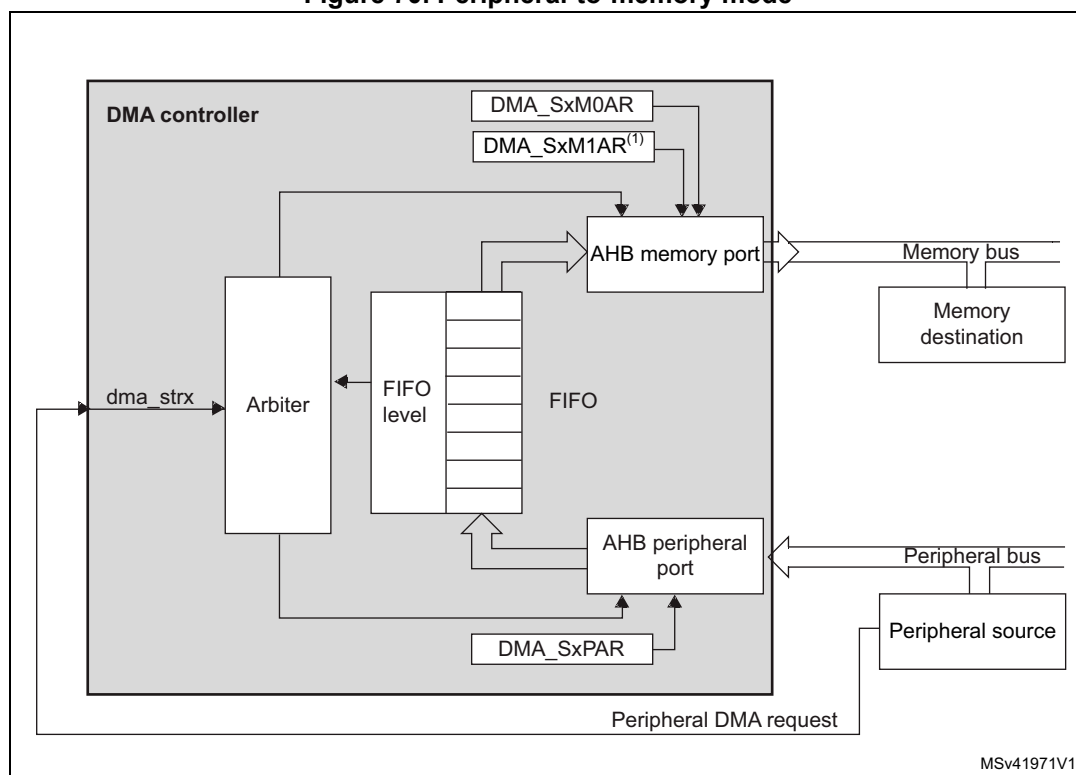

When the threshold level of the FIFO is reached, the contents of the FIFO are drained and stored into the destination.

The transfer stops once the DMA\_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA\_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA\_SxFCR register is '0'), the threshold level of the FIFO is not used: after each single data transfer from the peripheral to the FIFO, the corresponding data are immediately drained and stored into the destination.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Figure 70. Peripheral-to-memory mode**

1. For double-buffer mode.

### Memory-to-peripheral mode

Figure 71 describes this mode.

When this mode is enabled (by setting the EN bit in the DMA\_SxCR register), the stream immediately initiates transfers from the source to entirely fill the FIFO.

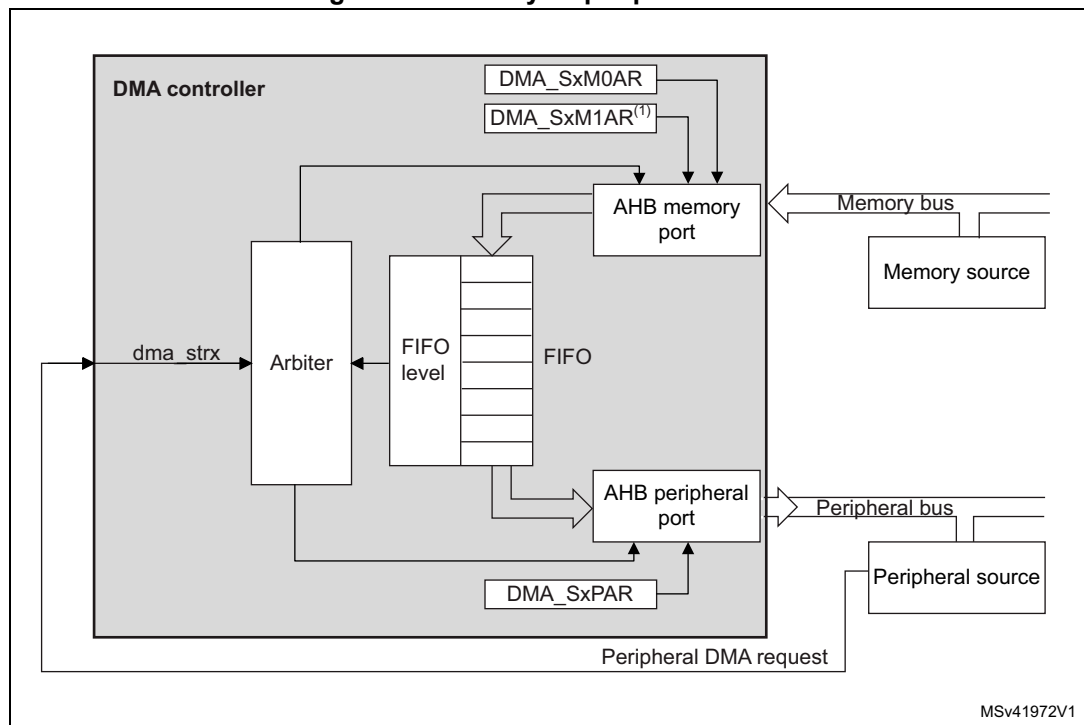

Each time a peripheral request occurs, the contents of the FIFO are drained and stored into the destination. When the level of the FIFO is lower than or equal to the predefined threshold level, the FIFO is fully reloaded with data from the memory.

The transfer stops once the DMA\_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA\_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA\_SxFCR register is '0'), the threshold level of the FIFO is not used. Once the stream is enabled, the DMA preloads the first data to transfer into an internal FIFO. As soon as the peripheral requests a data transfer, the DMA transfers the preloaded value into the configured destination. It then reloads again the empty internal FIFO with the next data to be transfer. The preloaded data size corresponds to the value of the PSIZE bitfield in the DMA\_SxCR register.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

Figure 71. Memory-to-peripheral mode

1. For double-buffer mode.

### Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This is the memory-to-memory mode, described in [Figure 72](#).

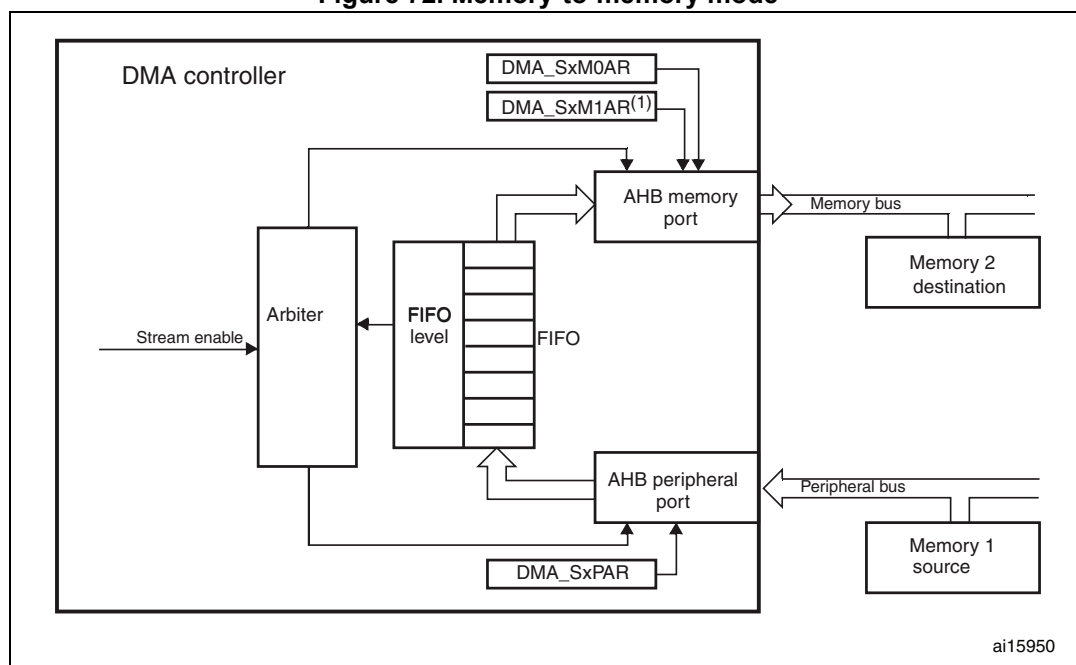

When the stream is enabled by setting the Enable bit (EN) in the DMA\_SxCR register, the stream immediately starts to fill the FIFO up to the threshold level. When the threshold level is reached, the FIFO contents are drained and stored into the destination.

The transfer stops once the DMA\_SxNDTR register reaches zero or when the EN bit in the DMA\_SxCR register is cleared by software.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

*Note:* When memory-to-memory mode is used, the Circular and direct modes are not allowed.

**Figure 72. Memory-to-memory mode**

1. For double-buffer mode.

### 15.3.9 Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented or kept constant after each transfer depending on the PINC and MINC bits in the DMA\_SxCR register.

Disabling the Increment mode is useful when the peripheral source or destination data are accessed through a single register.

If the Increment mode is enabled, the address of the next transfer will be the address of the previous one incremented by 1 (for bytes), 2 (for half-words) or 4 (for words) depending on the data width programmed in the PSIZE or MSIZE bits in the DMA\_SxCR register.

In order to optimize the packing operation, it is possible to fix the increment offset size for the peripheral address whatever the size of the data transferred on the AHB peripheral port. The PINCOS bit in the DMA\_SxCR register is used to align the increment offset size with the data size on the peripheral AHB port, or on a 32-bit address (the address is then incremented by 4). The PINCOS bit has an impact on the AHB peripheral port only.

If the PINCOS bit is set, the address of the following transfer is the address of the previous one incremented by 4 (automatically aligned on a 32-bit address), whatever the PSIZE value. The AHB memory port, however, is not impacted by this operation.

### 15.3.10 Circular mode

The Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA\_SxCR register.

When the circular mode is activated, the number of data items to be transferred is automatically reloaded with the initial value programmed during the stream configuration phase, and the DMA requests continue to be served.

*Note:* In the circular mode, it is mandatory to respect the following rule in case of a burst mode configured for memory:

$DMA\_SxNDTR = \text{Multiple of } ((Mburst\ beat) \times (Msize)/(Psize)), \text{ where:}$

- $(Mburst\ beat) = 4, 8 \text{ or } 16$  (depending on the MBURST bits in the DMA\_SxCR register)
- $((Msize)/(Psize)) = 1, 2, 4, 1/2 \text{ or } 1/4$  (Msize and Psize represent the MSIZE and PSIZE bits in the DMA\_SxCR register. They are byte dependent)
- $DMA\_SxNDTR = \text{Number of data items to transfer on the AHB peripheral port}$

*For example: Mburst beat = 8 (INCR8), MSIZE = '00' (byte) and PSIZE = '01' (half-word), in this case: DMA\_SxNDTR must be a multiple of  $(8 \times 1/2 = 4)$ .*

*If this formula is not respected, the DMA behavior and data integrity are not guaranteed.*

*NDTR must also be a multiple of the Peripheral burst size multiplied by the peripheral data size, otherwise this could result in a bad DMA behavior.*

### 15.3.11 Double buffer mode

This mode is available for all the DMA1 and DMA2 streams.

The Double buffer mode is enabled by setting the DBM bit in the DMA\_SxCR register.

A double-buffer stream works as a regular (single buffer) stream with the difference that it has two memory pointers. When the Double buffer mode is enabled, the Circular mode is automatically enabled (CIRC bit in DMA\_SxCR is don't care) and at each end of transaction, the memory pointers are swapped.

In this mode, the DMA controller swaps from one memory target to another at each end of transaction. This allows the software to process one memory area while the second memory area is being filled/used by the DMA transfer. The double-buffer stream can work in both directions (the memory can be either the source or the destination) as described in [Table 99: Source and destination address registers in double buffer mode \(DBM=1\)](#).

Note: In Double buffer mode, it is possible to update the base address for the AHB memory port on-the-fly (DMA\_SxM0AR or DMA\_SxM1AR) when the stream is enabled, by respecting the following conditions:

- When the CT bit is '0' in the DMA\_SxCR register, the DMA\_SxM1AR register can be written. Attempting to write to this register while CT = '1' sets an error flag (TEIF) and the stream is automatically disabled.
- When the CT bit is '1' in the DMA\_SxCR register, the DMA\_SxM0AR register can be written. Attempting to write to this register while CT = '0', sets an error flag (TEIF) and the stream is automatically disabled.

To avoid any error condition, it is advised to change the base address as soon as the TCIF flag is asserted because, at this point, the targeted memory must have changed from memory 0 to 1 (or from 1 to 0) depending on the value of CT in the DMA\_SxCR register in accordance with one of the two above conditions.

For all the other modes (except the Double buffer mode), the memory address registers are write-protected as soon as the stream is enabled.

**Table 99. Source and destination address registers in double buffer mode (DBM=1)**

Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
00	Peripheral-to-memory	DMA_SxPAR	DMA_SxM0AR / DMA_SxM1AR
01	Memory-to-peripheral	DMA_SxM0AR / DMA_SxM1AR	DMA_SxPAR
10	Not allowed <sup>(1)</sup>		
11	Reserved	-	-

1. When the Double buffer mode is enabled, the Circular mode is automatically enabled. Since the memory-to-memory mode is not compatible with the Circular mode, when the Double buffer mode is enabled, it is not allowed to configure the memory-to-memory mode.

### 15.3.12 Programmable data width, packing/unpacking, endianness

The number of data items to be transferred has to be programmed into DMA\_SxNDTR (number of data items to transfer bit, NDT) before enabling the stream (except when the flow controller is the peripheral, PFCTRL bit in DMA\_SxCR is set).

When using the internal FIFO, the data widths of the source and destination data are programmable through the PSIZE and MSIZE bits in the DMA\_SxCR register (can be 8-, 16- or 32-bit).

When PSIZE and MSIZE are not equal:

- The data width of the number of data items to transfer, configured in the DMA\_SxNDTR register is equal to the width of the peripheral bus (configured by the PSIZE bits in the DMA\_SxCR register). For instance, in case of peripheral-to-memory, memory-to-peripheral or memory-to-memory transfers and if the PSIZE[1:0] bits are configured for half-word, the number of bytes to be transferred is equal to 2 × NDT.
- The DMA controller only copes with little-endian addressing for both source and destination. This is described in [Table 100: Packing/unpacking & endian behavior \(bit PINC = MINC = 1\)](#).

This packing/unpacking procedure may present a risk of data corruption when the operation is interrupted before the data are completely packed/unpacked. So, to ensure data coherence, the stream may be configured to generate burst transfers: in this case, each

group of transfers belonging to a burst are indivisible (refer to [Section 15.3.13: Single and burst transfers](#)).

In direct mode (DMDIS = 0 in the DMA\_SxFCR register), the packing/unpacking of data is not possible. In this case, it is not allowed to have different source and destination transfer data widths: both are equal and defined by the PSIZE bits in the DMA\_SxCR MSIZE bits are don't care).

**Table 100. Packing/unpacking & endian behavior (bit PINC = MINC = 1)**

AHB memory port width	AHB peripheral port width	Number of data items to transfer (NDT)	Memory transfer number	Memory port address / byte lane	Peripheral transfer number	Peripheral port address / byte lane	
						PINCOS = 1	PINCOS = 0
8	8	4	1	0x0 / B0[7:0]	1	0x0 / B0[7:0]	0x0 / B0[7:0]
			2	0x1 / B1[7:0]	2	0x4 / B1[7:0]	0x1 / B1[7:0]
			3	0x2 / B2[7:0]	3	0x8 / B2[7:0]	0x2 / B2[7:0]
			4	0x3 / B3[7:0]	4	0xC / B3[7:0]	0x3 / B3[7:0]
8	16	2	1	0x0 / B0[7:0]	1	0x0 / B1 B0[15:0]	0x0 / B1 B0[15:0]
			2	0x1 / B1[7:0]	2	0x4 / B3 B2[15:0]	0x2 / B3 B2[15:0]
			3	0x2 / B2[7:0]			
			4	0x3 / B3[7:0]

			2	0x1 / B1[7:0]			
			3	0x2 / B2[7:0]			
			4	0x3 / B3[7:0]			
16	8	4	1	0x0 / B1 B0[15:0]	1	0x0 / B0[7:0]	0x0 / B0[7:0]
			2	0x2 / B3 B2[15:0]	2	0x4 / B1[7:0]	0x1 / B1[7:0]
			3		3	0x8 / B2[7:0]	0x2 / B2[7:0]
			4		4	0xC / B3[7:0]	0x3 / B3[7:0]
16	16	2	1	0x0 / B1 B0[15:0]	1	0x0 / B1 B0[15:0]	0x0 / B1 B0[15:0]
			2	0x2 / B3 B2[15:0]	2	0x4 / B3 B2[15:0]	0x2 / B3 B2[15:0]
16	32	1	1	0x0 / B1 B0[15:0]	1	0x0 / B3 B2 B1 B0[31:0]	0x0 / B3 B2 B1 B0[31:0]
			2	0x2 / B3 B2[15:0]			
32	8	4	1	0x0 / B3 B2 B1 B0[31:0]	1	0x0 / B0[7:0]	0x0 / B0[7:0]
			2		2	0x4 / B1[7:0]	0x1 / B1[7:0]
			3		3	0x8 / B2[7:0]	0x2 / B2[7:0]
			4		4	0xC / B3[7:0]	0x3 / B3[7:0]
32	16	2	1	0x0 / B3 B2 B1 B0[31:0]	1	0x0 / B1 B0[15:0]	0x0 / B1 B0[15:0]
			2		2	0x4 / B3 B2[15:0]	0x2 / B3 B2[15:0]
32	32	1	1	0x0 / B3 B2 B1 B0 [31:0]	1	0x0 / B3 B2 B1 B0 [31:0]	0x0 / B3 B2 B1 B0[31:0]

*Note:* Peripheral port may be the source or the destination (it could also be the memory source in the case of memory-to-memory transfer).

PSIZE, MSIZE and NDT[15:0] have to be configured so as to ensure that the last transfer will not be incomplete. This can occur when the data width of the peripheral port (PSIZE bits) is lower than the data width of the memory port (MSIZE bits). This constraint is summarized in [Table 101](#).

Table 101. Restriction on NDT versus PSIZE and MSIZE

PSIZE[1:0] of DMA_SxCR	MSIZE[1:0] of DMA_SxCR	NDT[15:0] of DMA_SxNDTR
00 (8-bit)	01 (16-bit)	must be a multiple of 2
00 (8-bit)	10 (32-bit)	must be a multiple of 4
01 (16-bit)	10 (32-bit)	must be a multiple of 2

### 15.3.13 Single and burst transfers

The DMA controller can generate single transfers or incremental burst transfers of 4, 8 or 16 beats.

The size of the burst is configured by software independently for the two AHB ports by using the MBURST[1:0] and PBURST[1:0] bits in the DMA\_SxCR register.

The burst size indicates the number of beats in the burst, not the number of bytes transferred.

To ensure data coherence, each group of transfers that form a burst are indivisible: AHB transfers are locked and the arbiter of the AHB bus matrix does not degrant the DMA master during the sequence of the burst transfer.

Depending on the single or burst configuration, each DMA request initiates a different number of transfers on the AHB peripheral port:

- When the AHB peripheral port is configured for single transfers, each DMA request generates a data transfer of a byte, half-word or word depending on the PSIZE[1:0] bits in the DMA\_SxCR register
- When the AHB peripheral port is configured for burst transfers, each DMA request generates 4,8 or 16 beats of byte, half word or word transfers depending on the PBURST[1:0] and PSIZE[1:0] bits in the DMA\_SxCR register.

The same as above has to be considered for the AHB memory port considering the MBURST and MSIZE bits.

In direct mode, the stream can only generate single transfers and the MBURST[1:0] and PBURST[1:0] bits are forced by hardware.

The address pointers (DMA\_SxPAR or DMA\_SxM0AR registers) must be chosen so as to ensure that all transfers within a burst block are aligned on the address boundary equal to the size of the transfer.

The burst configuration has to be selected in order to respect the AHB protocol, where bursts must *not* cross the 1 KB address boundary because the minimum address space that can be allocated to a single slave is 1 KB. This means that the 1 KB address boundary should not be crossed by a burst block transfer, otherwise an AHB error would be generated, that is not reported by the DMA registers.

### 15.3.14 FIFO

#### FIFO structure

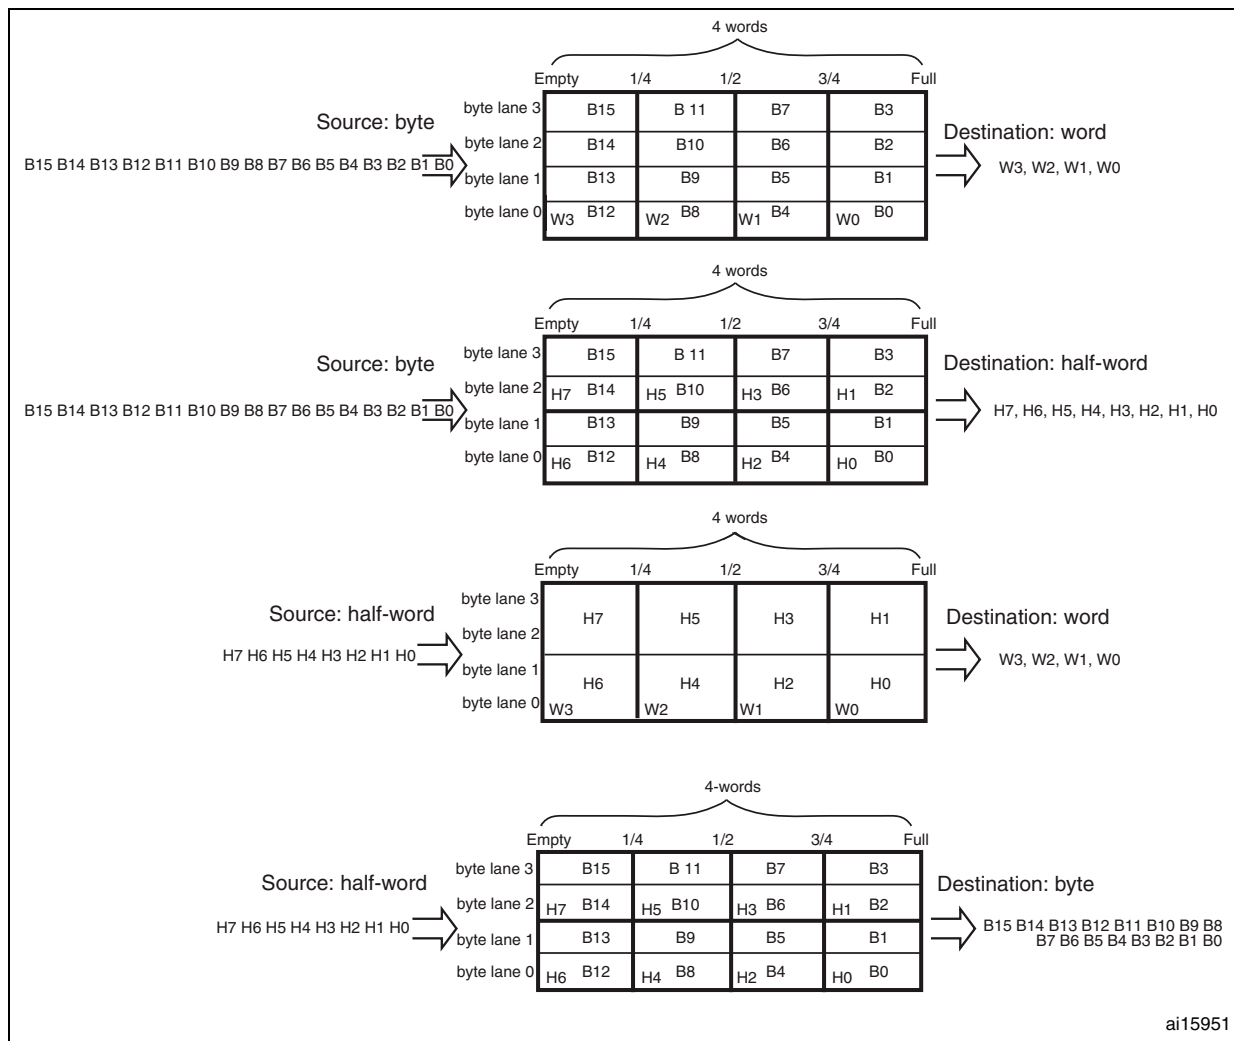

The FIFO is used to temporarily store data coming from the source before transmitting them to the destination.

Each stream has an independent 4-word FIFO and the threshold level is software-configurable between 1/4, 1/2, 3/4 or full.

To enable the use of the FIFO threshold level, the direct mode must be disabled by setting the DMDIS bit in the DMA\_SxFCR register.

The structure of the FIFO differs depending on the source and destination data widths, and is described in [Figure 73: FIFO structure](#).

Figure 73. FIFO structure

### FIFO threshold and burst configuration

Caution is required when choosing the FIFO threshold (bits FTH[1:0] of the DMA\_SxFCR register) and the size of the memory burst (MBURST[1:0] of the DMA\_SxCR register): The content pointed by the FIFO threshold must exactly match an integer number of memory burst transfers. If this is not in the case, a FIFO error (flag FEIFx of the DMA\_HISR or DMA\_LISR register) will be generated when the stream is enabled, then the stream will be automatically disabled. The allowed and forbidden configurations are described in [Table 102](#). The forbidden configurations are highlighted in gray in the table.

**Table 102. FIFO threshold configurations**

MSIZE	FIFO level	MBURST = INCR4	MBURST = INCR8	MBURST = INCR16
Byte	1/4	1 burst of 4 beats	forbidden	forbidden
	1/2	2 bursts of 4 beats	1 burst of 8 beats	
	3/4	3 bursts of 4 beats	forbidden	
	Full	4 bursts of 4 beats	2 bursts of 8 beats	1 burst of 16 beats
Half-word	1/4	forbidden	forbidden	forbidden
	1/2	1 burst of 4 beats		
	3/4	forbidden		
	Full	2 bursts of 4 beats	1 burst of 8 beats	
Word	1/4	forbidden	forbidden	forbidden
	1/2			
	3/4			
	Full	1 burst of 4 beats		

In all cases, the burst size multiplied by the data size must not exceed the FIFO size (data size can be: 1 (byte), 2 (half-word) or 4 (word)).

Incomplete Burst transfer at the end of a DMA transfer may happen if one of the following conditions occurs:

- For the AHB peripheral port configuration: the total number of data items (set in the DMA\_SxNDTR register) is not a multiple of the burst size multiplied by the data size
- For the AHB memory port configuration: the number of remaining data items in the FIFO to be transferred to the memory is not a multiple of the burst size multiplied by the data size

In such cases, the remaining data to be transferred will be managed in single mode by the DMA, even if a burst transaction was requested during the DMA stream configuration.

*Note: When burst transfers are requested on the peripheral AHB port and the FIFO is used (DMDIS = 1 in the DMA\_SxCR register), it is mandatory to respect the following rule to avoid permanent underrun or overrun conditions, depending on the DMA stream direction:*  
*If (PBURST × PSIZE) = FIFO\_SIZE (4 words), FIFO\_Threshold = 3/4 is forbidden with PSIZE = 1, 2 or 4 and PBURST = 4, 8 or 16.*  
*This rule ensures that enough FIFO space at a time will be free to serve the request from the peripheral.*

### FIFO flush

The FIFO can be flushed when the stream is disabled by resetting the EN bit in the DMA\_SxCR register and when the stream is configured to manage peripheral-to-memory or memory-to-memory transfers: If some data are still present in the FIFO when the stream is disabled, the DMA controller continues transferring the remaining data to the destination (even though stream is effectively disabled). When this flush is completed, the transfer complete status bit (TCIFx) in the DMA\_LISR or DMA\_HISR register is set.

The remaining data counter DMA\_SxNDTR keeps the value in this case to indicate how many data items are currently available in the destination memory.

Note that during the FIFO flush operation, if the number of remaining data items in the FIFO to be transferred to memory (in bytes) is less than the memory data width (for example 2 bytes in FIFO while MSIZE is configured to word), data will be sent with the data width set in the MSIZE bit in the DMA\_SxCR register. This means that memory will be written with an undesired value. The software may read the DMA\_SxNDTR register to determine the memory area that contains the good data (start address and last address).

If the number of remaining data items in the FIFO is lower than a burst size (if the MBURST bits in DMA\_SxCR register are set to configure the stream to manage burst on the AHB memory port), single transactions will be generated to complete the FIFO flush.

### Direct mode

By default, the FIFO operates in direct mode (DMDIS bit in the DMA\_SxFCR is reset) and the FIFO threshold level is not used. This mode is useful when the system requires an immediate and single transfer to or from the memory after each DMA request.

When the DMA is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

To avoid saturating the FIFO, it is recommended to configure the corresponding stream with a high priority.

This mode is restricted to transfers where:

- The source and destination transfer widths are equal and both defined by the PSIZE[1:0] bits in DMA\_SxCR (MSIZE[1:0] bits are don't care)
- Burst transfers are not possible (PBURST[1:0] and MBURST[1:0] bits in DMA\_SxCR are don't care)

Direct mode must not be used when implementing memory-to-memory transfers.

## 15.3.15 DMA transfer completion

Different events can generate an end of transfer by setting the TCIFx bit in the DMA\_LISR or DMA\_HISR status register:

- In DMA flow controller mode:
  - The DMA\_SxNDTR counter has reached zero in the memory-to-peripheral mode
  - The stream is disabled before the end of transfer (by clearing the EN bit in the DMA\_SxCR register) and (when transfers are peripheral-to-memory or memory-

to-memory) all the remaining data have been flushed from the FIFO into the memory

- In Peripheral flow controller mode:
  - The last external burst or single request has been generated from the peripheral and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory
  - The stream is disabled by software, and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory

*Note:* The transfer completion is dependent on the remaining data in FIFO to be transferred into memory only in the case of peripheral-to-memory mode. This condition is not applicable in memory-to-peripheral mode.

If the stream is configured in noncircular mode, after the end of the transfer (that is when the number of data to be transferred reaches zero), the DMA is stopped (EN bit in DMA\_SxCR register is cleared by Hardware) and no DMA request is served unless the software reprograms the stream and re-enables it (by setting the EN bit in the DMA\_SxCR register).

### 15.3.16 DMA transfer suspension

At any time, a DMA transfer can be suspended to be restarted later on or to be definitively disabled before the end of the DMA transfer.

There are two cases:

- The stream disables the transfer with no later-on restart from the point where it was stopped. There is no particular action to do, except to clear the EN bit in the DMA\_SxCR register to disable the stream. The stream may take time to be disabled (ongoing transfer is completed first). The transfer complete interrupt flag (TCIF in the DMA\_LISR or DMA\_HISR register) is set in order to indicate the end of transfer. The value of the EN bit in DMA\_SxCR is now '0' to confirm the stream interruption. The DMA\_SxNDTR register contains the number of remaining data items at the moment when the stream was stopped so that the software can determine how many data items have been transferred before the stream was interrupted.
- The stream suspends the transfer before the number of remaining data items to be transferred in the DMA\_SxNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the stream. In order to restart from the point where the transfer was stopped, the software has to read the DMA\_SxNDTR register after disabling the stream by writing the EN bit in DMA\_SxCR register (and then checking that it is at '0') to know the number of data items already collected. Then:
  - The peripheral and/or memory addresses have to be updated in order to adjust the address pointers
  - The SxNDTR register has to be updated with the remaining number of data items to be transferred (the value read when the stream was disabled)
  - The stream may then be re-enabled to restart the transfer from the point it was stopped

*Note:* Note that a Transfer complete interrupt flag (TCIF in DMA\_LISR or DMA\_HISR) is set to indicate the end of transfer due to the stream interruption.

### 15.3.17 Flow controller

The entity that controls the number of data to be transferred is known as the flow controller. This flow controller is configured independently for each stream using the PFCTRL bit in the DMA\_SxCR register.

The flow controller can be:

- The DMA controller: in this case, the number of data items to be transferred is programmed by software into the DMA\_SxNDTR register before the DMA stream is enabled.
- The peripheral source or destination: this is the case when the number of data items to be transferred is unknown. The peripheral indicates by hardware to the DMA controller when the last data are being transferred. This feature is only supported for peripherals which are able to signal the end of the transfer, that is:

When the peripheral flow controller is used for a given stream, the value written into the DMA\_SxNDTR has no effect on the DMA transfer. Actually, whatever the value written, it will be forced by hardware to 0xFFFF as soon as the stream is enabled, to respect the following schemes:

- Anticipated stream interruption: EN bit in DMA\_SxCR register is reset to 0 by the software to stop the stream before the last data hardware signal (single or burst) is sent by the peripheral. In such a case, the stream is switched off and the FIFO flush is triggered in the case of a peripheral-to-memory DMA transfer. The TCIFx flag of the corresponding stream is set in the status register to indicate the DMA completion. To know the number of data items transferred during the DMA transfer, read the DMA\_SxNDTR register and apply the following formula:
  - $\text{Number\_of\_data\_transferred} = 0xFFFF - \text{DMA\_SxNDTR}$
- Normal stream interruption due to the reception of a last data hardware signal: the stream is automatically interrupted when the peripheral requests the last transfer (single or burst) and when this transfer is complete. the TCIFx flag of the corresponding stream is set in the status register to indicate the DMA transfer completion. To know the number of data items transferred, read the DMA\_SxNDTR register and apply the same formula as above.
- The DMA\_SxNDTR register reaches 0: the TCIFx flag of the corresponding stream is set in the status register to indicate the forced DMA transfer completion. The stream is automatically switched off even though the last data hardware signal (single or burst) has not been yet asserted. The already transferred data will not be lost. This means that a maximum of 65535 data items can be managed by the DMA in a single transaction, even in peripheral flow control mode.

*Note:* When configured in memory-to-memory mode, the DMA is always the flow controller and the PFCTRL bit is forced to 0 by hardware.

*The Circular mode is forbidden in the peripheral flow controller mode.*

### 15.3.18 Summary of the possible DMA configurations

Table 103 summarizes the different possible DMA configurations. The forbidden configurations are highlighted in gray in the table.

**Table 103. Possible DMA configurations**

DMA transfer mode	Source	Destination	Flow controller	Circular mode	Transfer type	Direct mode	Double buffer mode
Peripheral-to-memory	AHB peripheral port	AHB memory port	DMA	possible	single	possible	possible
					burst	forbidden	
			Peripheral	forbidden	single	possible	forbidden
					burst	forbidden	
Memory-to-peripheral	AHB memory port	AHB peripheral port	DMA	possible	single	possible	possible
					burst	forbidden	
			Peripheral	forbidden	single	possible	forbidden
					burst	forbidden	
Memory-to-memory	AHB peripheral port	AHB memory port	DMA only	forbidden	single	forbidden	forbidden
					burst		

### 15.3.19 Stream configuration procedure

The following sequence should be followed to configure a DMA stream x (where x is the stream number):

1. If the stream is enabled, disable it by resetting the EN bit in the DMA\_SxCR register, then read this bit in order to confirm that there is no ongoing stream operation. Writing this bit to 0 is not immediately effective since it is actually written to 0 once all the current transfers have finished. When the EN bit is read as 0, this means that the stream is ready to be configured. It is therefore necessary to wait for the EN bit to be cleared before starting any stream configuration. All the stream dedicated bits set in the status register (DMA\_LISR and DMA\_HISR) from the previous data block DMA transfer should be cleared before the stream can be re-enabled.
2. Set the peripheral port register address in the DMA\_SxPAR register. The data will be moved from/ to this address to/ from the peripheral port after the peripheral event.
3. Set the memory address in the DMA\_SxMA0R register (and in the DMA\_SxMA1R register in the case of a double buffer mode). The data will be written to or read from this memory after the peripheral event.
4. Configure the total number of data items to be transferred in the DMA\_SxNDTR register. After each peripheral event or each beat of the burst, this value is decremented.
5. Use DMAMux1 to route a DMA request line to the DMA channel.
6. If the peripheral is intended to be the flow controller and if it supports this feature, set the PFCTRL bit in the DMA\_SxCR register.
7. Configure the stream priority using the PL[1:0] bits in the DMA\_SxCR register.
8. Configure the FIFO usage (enable or disable, threshold in transmission and reception)

9. Configure the data transfer direction, peripheral and memory incremented/fixed mode, single or burst transactions, peripheral and memory data widths, Circular mode, Double buffer mode and interrupts after half and/or full transfer, and/or errors in the DMA\_SxCR register.
10. Activate the stream by setting the EN bit in the DMA\_SxCR register.

As soon as the stream is enabled, it can serve any DMA request from the peripheral connected to the stream.

Once half the data have been transferred on the AHB destination port, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

---

**Warning:** To switch off a peripheral connected to a DMA stream request, it is mandatory to, first, switch off the DMA stream to which the peripheral is connected, then to wait for EN bit = 0. Only then can the peripheral be safely disabled.

---

### 15.3.20 Error management

The DMA controller can detect the following errors:

- **Transfer error:** the transfer error interrupt flag (TEIFx) is set when:
  - A bus error occurs during a DMA read or a write access
  - A write access is requested by software on a memory address register in Double buffer mode whereas the stream is enabled and the current target memory is the one impacted by the write into the memory address register (refer to [Section 15.3.11: Double buffer mode](#))
- **FIFO error:** the FIFO error interrupt flag (FEIFx) is set if:
  - A FIFO underrun condition is detected
  - A FIFO overrun condition is detected (no detection in memory-to-memory mode because requests and transfers are internally managed by the DMA)
  - The stream is enabled while the FIFO threshold level is not compatible with the size of the memory burst (refer to [Table 102: FIFO threshold configurations](#))
- **Direct mode error:** the direct mode error interrupt flag (DMEIFx) can only be set in the peripheral-to-memory mode while operating in direct mode and when the MINC bit in the DMA\_SxCR register is cleared. This flag is set when a DMA request occurs while the previous data have not yet been fully transferred into the memory (because the memory bus was not granted). In this case, the flag indicates that 2 data items were be transferred successively to the same destination address, which could be an issue if the destination is not able to manage this situation

In direct mode, the FIFO error flag can also be set under the following conditions:

- In the peripheral-to-memory mode, the FIFO can be saturated (overrun) if the memory bus is not granted for several peripheral requests
- In the memory-to-peripheral mode, an underrun condition may occur if the memory bus has not been granted before a peripheral request occurs

If the TEIFx or the FEIFx flag is set due to incompatibility between burst size and FIFO threshold level, the faulty stream is automatically disabled through a hardware clear of its EN bit in the corresponding stream configuration register (DMA\_SxCR).

If the DMEIFx or the FEIFx flag is set due to an overrun or underrun condition, the faulty stream is not automatically disabled and it is up to the software to disable or not the stream by resetting the EN bit in the DMA\_SxCR register. This is because there is no data loss when this kind of errors occur.

When the stream's error interrupt flag (TEIF, FEIF, DMEIF) in the DMA\_LISR or DMA\_HISR register is set, an interrupt is generated if the corresponding interrupt enable bit (TEIE, FEIE, DMIE) in the DMA\_SxCR or DMA\_SxFCR register is set.

*Note:* When a FIFO overrun or underrun condition occurs, the data are not lost because the peripheral request is not acknowledged by the stream until the overrun or underrun condition is cleared. If this acknowledge takes too much time, the peripheral itself may detect an overrun or underrun condition of its internal buffer and data might be lost.

## 15.4 DMA interrupts

For each DMA stream, an interrupt can be produced on the following events:

- Half-transfer reached
- Transfer complete
- Transfer error
- FIFO error (overrun, underrun or FIFO level error)
- Direct mode error

Separate interrupt enable control bits are available for flexibility as shown in [Table 104](#).

**Table 104. DMA interrupt requests**

Interrupt event	Event flag	Enable control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE
FIFO overrun/underrun	FEIF	FEIE
Direct mode error	DMEIF	DMEIE

*Note:* Before setting an Enable control bit to '1', the corresponding event flag should be cleared, otherwise an interrupt is immediately generated.

## 15.5 DMA registers

The DMA registers have to be accessed by words (32 bits).

### 15.5.1 DMA low interrupt status register (DMA\_LISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TCIF3	HTIF3	TEIF3	DMEIF3	Res.	FEIF3	TCIF2	HTIF2	TEIF2	DMEIF2	Res.	FEIF2
r	r	r	r	r	r	r	r		r	r	r	r	r		r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	TCIF1	HTIF1	TEIF1	DMEIF1	Res.	FEIF1	TCIF0	HTIF0	TEIF0	DMEIF0	Res.	FEIF0
r	r	r	r	r	r	r	r		r	r	r	r	r		r

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIFx**: Stream x transfer complete interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No transfer complete event on stream x

1: A transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIFx**: Stream x half transfer interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No half transfer event on stream x

1: A half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIFx**: Stream x transfer error interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No transfer error on stream x

1: A transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIFx**: Stream x direct mode error interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No Direct Mode Error on stream x

1: A Direct Mode Error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIFx**: Stream x FIFO error interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No FIFO Error event on stream x

1: A FIFO Error event occurred on stream x

### 15.5.2 DMA high interrupt status register (DMA\_HISR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TCIF7	HTIF7	TEIF7	DMEIF7	Res.	FEIF7	TCIF6	HTIF6	TEIF6	DMEIF6	Res.	FEIF6
				r	r	r	r		r	r	r	r	r		r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	TCIF5	HTIF5	TEIF5	DMEIF5	Res.	FEIF5	TCIF4	HTIF4	TEIF4	DMEIF4	Res.	FEIF4
				r	r	r	r		r	r	r	r	r		r

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIFx**: Stream x transfer complete interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No transfer complete event on stream x

1: A transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIFx**: Stream x half transfer interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No half transfer event on stream x

1: A half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIFx**: Stream x transfer error interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No transfer error on stream x

1: A transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIFx**: Stream x direct mode error interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No Direct mode error on stream x

1: A Direct mode error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIFx**: Stream x FIFO error interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No FIFO error event on stream x

1: A FIFO error event occurred on stream x

### 15.5.3 DMA low interrupt flag clear register (DMA\_LIFCR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CTCIF3	CHTIF3	CTEIF3	CDMEIF3	Res.	CFEIF3	CTCIF2	CHTIF2	CTEIF2	CDMEIF2	Res.	CFEIF2
				w	w	w	w		w	w	w	w	w		w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	CTCIF1	CHTIF1	CTEIF1	CDMEIF1	Res.	CFEIF1	CTCIF0	CHTIF0	CTEIF0	CDMEIF0	Res.	CFEIF0
				w	w	w	w		w	w	w	w	w		w

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIFx**: Stream x clear transfer complete interrupt flag (x = 3..0)  
 Writing 1 to this bit clears the corresponding TCIFx flag in the DMA\_LISR register

Bits 26, 20, 10, 4 **CHTIFx**: Stream x clear half transfer interrupt flag (x = 3..0)  
 Writing 1 to this bit clears the corresponding HTIFx flag in the DMA\_LISR register

Bits 25, 19, 9, 3 **CTEIFx**: Stream x clear transfer error interrupt flag (x = 3..0)  
 Writing 1 to this bit clears the corresponding TEIFx flag in the DMA\_LISR register

Bits 24, 18, 8, 2 **CDMEIFx**: Stream x clear direct mode error interrupt flag (x = 3..0)  
 Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA\_LISR register

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIFx**: Stream x clear FIFO error interrupt flag (x = 3..0)  
 Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA\_LISR register

### 15.5.4 DMA high interrupt flag clear register (DMA\_HIFCR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				w	w	w	w		w	w	w	w	w		w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	CTCIF5	CHTIF5	CTEIF5	CDMEIF5	Res.	CFEIF5	CTCIF4	CHTIF4	CTEIF4	CDMEIF4	Res.	CFEIF4
				w	w	w	w		w	w	w	w	w		w

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIFx**: Stream x clear transfer complete interrupt flag (x = 7..4)  
 Writing 1 to this bit clears the corresponding TCIFx flag in the DMA\_HISR register

Bits 26, 20, 10, 4 **CHTIFx**: Stream x clear half transfer interrupt flag (x = 7..4)  
 Writing 1 to this bit clears the corresponding HTIFx flag in the DMA\_HISR register

Bits 25, 19, 9, 3 **CTEIFx**: Stream x clear transfer error interrupt flag (x = 7..4)  
 Writing 1 to this bit clears the corresponding TEIFx flag in the DMA\_HISR register

Bits 24, 18, 8, 2 **CDMEIFx**: Stream x clear direct mode error interrupt flag (x = 7..4)  
 Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA\_HISR register

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIFx**: Stream x clear FIFO error interrupt flag (x = 7..4)  
 Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA\_HISR register

### 15.5.5 DMA stream x configuration register (DMA\_SxCR) (x = 0..7)

This register is used to configure the concerned stream.

Address offset:  $0x10 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	MBURST [1:0]		PBURST[1:0]		Res.	CT	DBM	PL[1:0]	
							rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PINCOS	MSIZE[1:0]		PSIZE[1:0]		MINC	PINC	CIRC	DIR[1:0]		PFCTRL	TCIE	HTIE	TEIE	DMEIE	EN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:23 **MBURST**: Memory burst transfer configuration

These bits are set and cleared by software.

00: single transfer

01: INCR4 (incremental burst of 4 beats)

10: INCR8 (incremental burst of 8 beats)

11: INCR16 (incremental burst of 16 beats)

These bits are protected and can be written only if EN is '0'

In direct mode, these bits are forced to 0x0 by hardware as soon as bit EN= '1'.

Bits 22:21 **PBURST[1:0]**: Peripheral burst transfer configuration

These bits are set and cleared by software.

00: single transfer

01: INCR4 (incremental burst of 4 beats)

10: INCR8 (incremental burst of 8 beats)

11: INCR16 (incremental burst of 16 beats)

These bits are protected and can be written only if EN is '0'

In direct mode, these bits are forced to 0x0 by hardware.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CT**: Current target (only in double buffer mode)

This bits is set and cleared by hardware. It can also be written by software.

0: The current target memory is Memory 0 (addressed by the DMA\_SxM0AR pointer)

1: The current target memory is Memory 1 (addressed by the DMA\_SxM1AR pointer)

This bit can be written only if EN is '0' to indicate the target memory area of the first transfer.

Once the stream is enabled, this bit operates as a status flag indicating which memory area is the current target.

Bit 18 **DBM**: Double buffer mode

This bit is set and cleared by software.

0: No buffer switching at the end of transfer

1: Memory target switched at the end of the DMA transfer

This bit is protected and can be written only if EN is '0'.

Bits 17:16 **PL[1:0]**: Priority level

These bits are set and cleared by software.

00: Low

01: Medium

10: High

11: Very high

These bits are protected and can be written only if EN is '0'.

Bit 15 **PINCOS**: Peripheral increment offset size

This bit is set and cleared by software

0: The offset size for the peripheral address calculation is linked to the PSIZE

1: The offset size for the peripheral address calculation is fixed to 4 (32-bit alignment).

This bit has no meaning if bit PINC = '0'.

This bit is protected and can be written only if EN = '0'.

This bit is forced low by hardware when the stream is enabled (bit EN = '1') if the direct mode is selected or if PBURST are different from "00".

Bits 14:13 **MSIZE[1:0]**: Memory data size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: reserved

These bits are protected and can be written only if EN is '0'.

In direct mode, MSIZE is forced by hardware to the same value as PSIZE as soon as bit EN = '1'.

Bits 12:11 **PSIZE[1:0]**: Peripheral data size

These bits are set and cleared by software.

00: Byte (8-bit)

01: Half-word (16-bit)

10: Word (32-bit)

11: reserved

These bits are protected and can be written only if EN is '0'

Bit 10 **MINC**: Memory increment mode

This bit is set and cleared by software.

0: Memory address pointer is fixed

1: Memory address pointer is incremented after each data transfer (increment is done according to MSIZE)

This bit is protected and can be written only if EN is '0'.

Bit 9 **PINC**: Peripheral increment mode

This bit is set and cleared by software.

0: Peripheral address pointer is fixed

1: Peripheral address pointer is incremented after each data transfer (increment is done according to PSIZE)

This bit is protected and can be written only if EN is '0'.

Bit 8 **CIRC**: Circular mode

This bit is set and cleared by software and can be cleared by hardware.

0: Circular mode disabled

1: Circular mode enabled

When the peripheral is the flow controller (bit PFCTRL=1) and the stream is enabled (bit EN=1), then this bit is automatically forced by hardware to 0.

It is automatically forced by hardware to 1 if the DBM bit is set, as soon as the stream is enabled (bit EN = '1').

Bits 7:6 **DIR[1:0]**: Data transfer direction

These bits are set and cleared by software.

00: Peripheral-to-memory

01: Memory-to-peripheral

10: Memory-to-memory

11: reserved

These bits are protected and can be written only if EN is '0'.

Bit 5 **PFCTRL**: Peripheral flow controller

This bit is set and cleared by software.

0: The DMA is the flow controller

1: The peripheral is the flow controller

This bit is protected and can be written only if EN is '0'.

When the memory-to-memory mode is selected (bits DIR[1:0]=10), then this bit is automatically forced to 0 by hardware.

Bit 4 **TCIE**: Transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disabled

1: TC interrupt enabled

Bit 3 **HTIE**: Half transfer interrupt enable

This bit is set and cleared by software.

0: HT interrupt disabled

1: HT interrupt enabled

Bit 2 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disabled

1: TE interrupt enabled

Bit 1 **DMEIE**: Direct mode error interrupt enable

This bit is set and cleared by software.

0: DME interrupt disabled

1: DME interrupt enabled

Bit 0 **EN**: Stream enable / flag stream ready when read low

This bit is set and cleared by software.

0: Stream disabled

1: Stream enabled

This bit may be cleared by hardware:

- on a DMA end of transfer (stream ready to be configured)
- if a transfer error occurs on the AHB master buses
- when the FIFO threshold on memory AHB port is not compatible with the size of the burst

When this bit is read as 0, the software is allowed to program the Configuration and FIFO bits registers. It is forbidden to write these registers when the EN bit is read as 1.

*Note: Before setting EN bit to '1' to start a new transfer, the event flags corresponding to the stream in DMA\_LISR or DMA\_HISR register must be cleared.*

### 15.5.6 DMA stream x number of data register (DMA\_SxNDTR) (x = 0..7)

Address offset:  $0x14 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: Number of data items to transfer

Number of data items to be transferred (0 up to 65535). This register can be written only when the stream is disabled. When the stream is enabled, this register is read-only, indicating the remaining data items to be transmitted. This register decrements after each DMA transfer.

Once the transfer has completed, this register can either stay at zero (when the stream is in normal mode) or be reloaded automatically with the previously programmed value in the following cases:

- when the stream is configured in Circular mode.
- when the stream is enabled again by setting EN bit to '1'

If the value of this register is zero, no transaction can be served even if the stream is enabled.

### 15.5.7 DMA stream x peripheral address register (DMA\_SxPAR) (x = 0..7)

Address offset:  $0x18 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:0 **PAR[31:0]**: Peripheral address

Base address of the peripheral data register from/to which the data will be read/written.

These bits are write-protected and can be written only when bit EN = '0' in the DMA\_SxCR register.

### 15.5.8 DMA stream x memory 0 address register (DMA\_SxM0AR) (x = 0..7)

Address offset:  $0x1C + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:0 **M0A[31:0]**: Memory 0 address

Base address of Memory area 0 from/to which the data will be read/written.

These bits are write-protected. They can be written only if:

- the stream is disabled (bit EN= '0' in the DMA\_SxCR register) or
- the stream is enabled (EN='1' in DMA\_SxCR register) and bit CT = '1' in the DMA\_SxCR register (in Double buffer mode).

### 15.5.9 DMA stream x memory 1 address register (DMA\_SxM1AR) (x = 0..7)

Address offset:  $0x20 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
M1A[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:0 **M1A[31:0]**: Memory 1 address (used in case of Double buffer mode)

Base address of Memory area 1 from/to which the data will be read/written.

This register is used only for the Double buffer mode.

These bits are write-protected. They can be written only if:

- the stream is disabled (bit EN= '0' in the DMA\_SxCR register) or
- the stream is enabled (EN='1' in DMA\_SxCR register) and bit CT = '0' in the DMA\_SxCR register.

### 15.5.10 DMA stream x FIFO control register (DMA\_SxFCR) (x = 0..7)

Address offset:  $0x24 + 0x24 \times stream\ number$

Reset value: 0x0000 0021

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FEIE	Res.	FS[2:0]			DMDIS	FTH[1:0]	
								rw		r	r	r	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FEIE**: FIFO error interrupt enable

This bit is set and cleared by software.

0: FE interrupt disabled

1: FE interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:3 **FS[2:0]**: FIFO status

These bits are read-only.

000:  $0 < fifo\_level < 1/4$

001:  $1/4 \leq fifo\_level < 1/2$

010:  $1/2 \leq fifo\_level < 3/4$

011:  $3/4 \leq fifo\_level < full$

100: FIFO is empty

101: FIFO is full

others: no meaning

These bits are not relevant in the direct mode (DMDIS bit is zero).

Bit 2 **DMDIS**: Direct mode disable

This bit is set and cleared by software. It can be set by hardware.

0: Direct mode enabled

1: Direct mode disabled

This bit is protected and can be written only if EN is '0'.

This bit is set by hardware if the memory-to-memory mode is selected (DIR bit in DMA\_SxCR are "10") and the EN bit in the DMA\_SxCR register is '1' because the direct mode is not allowed in the memory-to-memory configuration.

Bits 1:0 **FTH[1:0]**: FIFO threshold selection

These bits are set and cleared by software.

00: 1/4 full FIFO

01: 1/2 full FIFO

10: 3/4 full FIFO

11: full FIFO

These bits are not used in the direct mode when the DMIS value is zero.

These bits are protected and can be written only if EN is '0'.

15.5.11 DMA register map

Table 105 summarizes the DMA registers.

Table 105. DMA register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 16 Basic direct memory access controller (BDMA)

### 16.1 Introduction

Basic direct memory access (BDMA) controller is used in order to provide high-speed data transfer between peripherals and memory as well as memory to memory. Data can be quickly moved by DMA without any CPU actions. This keeps CPU resources free for other operations.

The BDMA controller has 8 channels in total, each dedicated to managing memory access requests from one or more peripherals. Each has an arbiter for handling the priority between DMA requests.

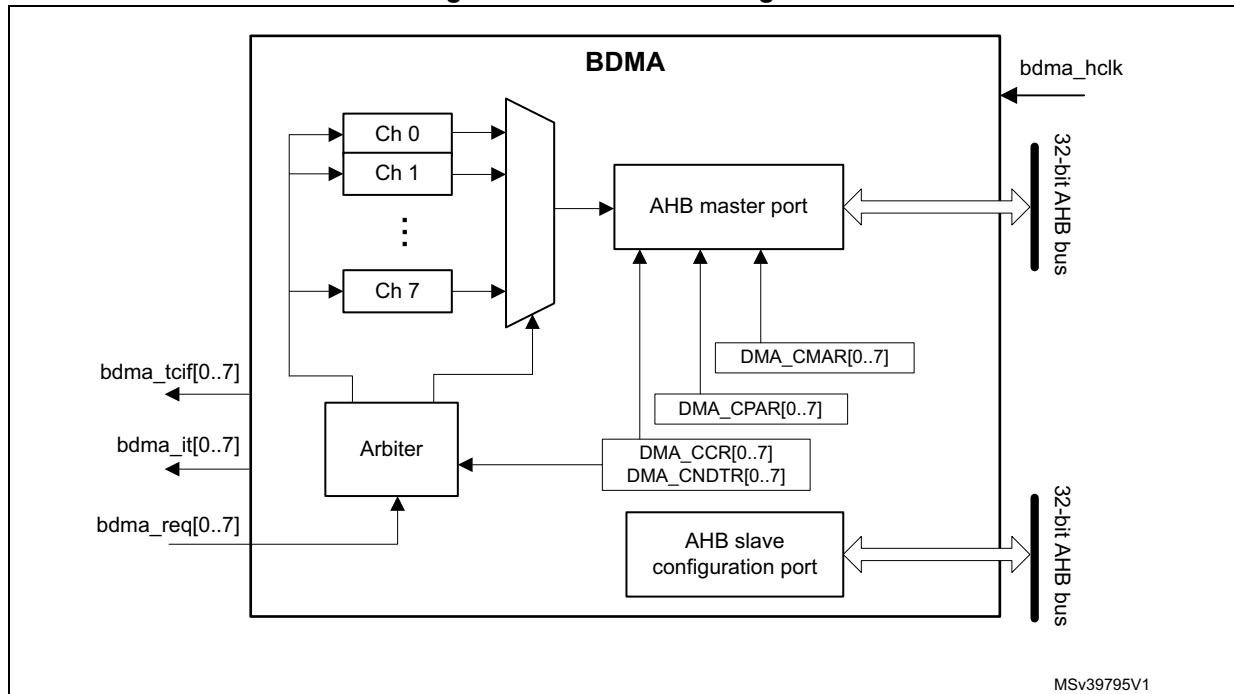

### 16.2 BDMA main features

- 8 independently configurable channels (requests)
- Each channel is connected to dedicated hardware DMA requests, software trigger is also supported on each channel. This configuration is done by software.
- Priorities between requests from channels of the BDMA controller are software programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (request 1 has priority over request 2, etc.)
- Independent source and destination transfer size (byte, half word, word), emulating packing and unpacking. Source/destination addresses must be aligned on the data size.
- Support for circular buffer management
- 3 event flags (DMA Half Transfer, DMA Transfer complete and DMA Transfer Error) logically ORed together in a single interrupt request for each channel
- Memory-to-memory transfer
- Peripheral-to-memory and memory-to-peripheral, and peripheral-to-peripheral transfers
- Access to D3-domain memories and peripherals as source and destination
- Programmable number of data to be transferred: up to 65535

### 16.3 BDMA functional description

The block diagram is shown in the following figure.

Figure 74. BDMA block diagram

The BDMA controller performs direct memory transfer by sharing the system bus with other system masters. The DMA request may stop the CPU access to the system bus for some bus cycles, when the CPU and DMA are targeting the same destination (memory or peripheral). The bus matrix implements round-robin scheduling, thus ensuring at least half of the system bus bandwidth (both to memory and peripheral) for the CPU.

#### 16.3.1 BDMA transactions

After an event, the peripheral sends a request signal to the BDMA Controller. The BDMA controller serves the request depending on the channel priorities. As soon as the BDMA Controller accesses the peripheral, an Acknowledge is sent to the peripheral by the BDMA Controller. The peripheral releases its request as soon as it gets the Acknowledge from the BDMA Controller. Once the request is de-asserted by the peripheral, the DMA Controller release the Acknowledge. If there are more requests, the peripheral can initiate the next transaction.

In summary, each BDMA transfer consists of three operations:

- The loading of data from the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the BDMA\_CPARx or BDMA\_CMARx register.

- The storage of the data loaded to the peripheral data register or a location in memory addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base peripheral/memory address programmed in the BDMA\_CPARx or BDMA\_CMARx register.
- The post-decrementing of the BDMA\_CNDTRx register, which contains the number of transactions that have still to be performed.

### 16.3.2 Arbiter

The arbiter manages the channel requests based on their priority and launches the peripheral/memory access sequences.

The priorities are managed in two stages:

- Software: each channel priority can be configured in the BDMA\_CCRx register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: if 2 requests have the same software priority level, the channel with the lowest number will get priority versus the channel with the highest number. For example, channel 2 gets priority over channel 4.

### 16.3.3 BDMA channels

Each channel can handle DMA transfer between a peripheral register located at a fixed address and a memory address. The amount of data to be transferred (up to 65535) is programmable. The register which contains the amount of data items to be transferred is decremented after each transaction.

#### Programmable data sizes

Transfer data sizes of the peripheral and memory are fully programmable through the PSIZE and MSIZE bits in the BDMA\_CCRx register.

#### Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented after each transaction depending on the PINC and MINC bits in the BDMA\_CCRx register. If incremented mode is enabled, the address of the next transfer will be the address of the previous one incremented by 1, 2 or 4 depending on the chosen data size. The first transfer address is the one programmed in the BDMA\_CPARx/BDMA\_CMARx registers. During transfer operations, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel is configured in non-circular mode, no DMA request is served after the last transfer (that is once the number of data items to be transferred has reached zero). In order to reload a new number of data items to be transferred into the BDMA\_CNDTRx register, the DMA channel must be disabled.

*Note:* If a DMA channel is disabled, the DMA registers are not reset. The DMA channel registers (BDMA\_CCRx, BDMA\_CPARx and BDMA\_CMARx) retain the initial values programmed during the channel configuration phase.

In circular mode, after the last transfer, the BDMA\_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the BDMA\_CPARx/BDMA\_CMARx registers.

### Channel configuration procedure

The following sequence should be followed to configure a DMA channel x (where x is the channel number).

1. Set the peripheral register address in the BDMA\_CPARx register. The data will be moved from/ to this address to/ from the memory after the peripheral event.
2. Set the memory address in the BDMA\_CMARx register. The data will be written to or read from this memory after the peripheral event.
3. Configure the total number of data to be transferred in the BDMA\_CNDTRx register. After each peripheral event, this value will be decremented.
4. Configure the channel priority using the PL[1:0] bits in the BDMA\_CCRx register
5. Configure data transfer direction, circular mode, peripheral & memory incremented mode, peripheral & memory data size, and interrupt after half and/or full transfer in the BDMA\_CCRx register
6. Activate the channel by setting the ENABLE bit in the BDMA\_CCRx register.

As soon as the channel is enabled, it can serve any DMA request from the peripheral connected on the channel.

Once half of the bytes are transferred, the half-transfer flag (HTIF) is set and an interrupt is generated if the Half-Transfer Interrupt Enable bit (HTIE) is set. At the end of the transfer, the Transfer Complete Flag (TCIF) is set and an interrupt is generated if the Transfer Complete Interrupt Enable bit (TCIE) is set.

### Circular mode

Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the BDMA\_CCRx register. When circular mode is activated, the number of data to be transferred is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

### Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This mode is called Memory to Memory mode.

If the MEM2MEM bit in the BDMA\_CCRx register is set, then the channel initiates transfers as soon as it is enabled by software by setting the Enable bit (EN) in the BDMA\_CCRx register. The transfer stops once the BDMA\_CNDTRx register reaches zero. Memory to Memory mode may not be used at the same time as Circular mode.

### 16.3.4 Programmable data width, data alignment and endians

When PSIZE and MSIZE are not equal, the DMA performs some data alignments as described in [Table 106: Programmable data width & endian behavior \(when bits PINC = MINC = 1\)](#).

**Table 106. Programmable data width & endian behavior (when bits PINC = MINC = 1)**

### Addressing an AHB peripheral that does not support byte or halfword write operations

When the DMA initiates an AHB byte or halfword write operation, the data are duplicated on the unused lanes of the HWDATA[31:0] bus. So when the used AHB slave peripheral does not support byte or halfword write operations (when HSIZE is not used by the peripheral) *and* does not generate any error, the DMA writes the 32 HWDATA bits as shown in the two examples below:

- To write the halfword “0xABCD”, the DMA sets the HWDATA bus to “0xABCDABCD” with HSIZE = HalfWord
- To write the byte “0xAB”, the DMA sets the HWDATA bus to “0xABABABAB” with HSIZE = Byte

Assuming that the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take the HSIZE data into account, it will transform any AHB byte or halfword operation into a 32-bit APB operation in the following manner:

- An AHB byte write operation of the data “0xB0” to 0x0 (or to 0x1, 0x2 or 0x3) will be converted to an APB word write operation of the data “0xB0B0B0B0” to 0x0
- An AHB halfword write operation of the data “0xB1B0” to 0x0 (or to 0x2) will be converted to an APB word write operation of the data “0xB1B0B1B0” to 0x0

For instance, to write the APB backup registers (16-bit registers aligned to a 32-bit address boundary), the software must configure the memory source size (MSIZE) to “16-bit” and the peripheral destination size (PSIZE) to “32-bit”.

### 16.3.5 Error management

A DMA transfer error can be generated by reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or a write access, the faulty channel is automatically disabled through a hardware clear of its EN bit in the corresponding Channel configuration register (BDMA\_CCRx). The channel's transfer error interrupt flag (TEIF) in the BDMA\_IFR register is set and an interrupt is generated if the transfer error interrupt enable bit (TEIE) in the BDMA\_CCRx register is set.

### 16.3.6 BDMA interrupts

An interrupt can be produced on a Half-transfer, Transfer complete or Transfer error for each DMA channel. Separate interrupt enable bits are available for flexibility.

**Table 107. BDMA interrupt requests**

Interrupt event	Event flag	Enable control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

The BDMA request mapping is in [Section 17.3.3: DMAMUX2 mapping](#).

## 16.4 BDMA registers

Refer to [Section 1.1 on page 98](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by bytes (8-bit), half-words (16-bit) or words (32-bit).

### 16.4.1 DMA interrupt status register (BDMA\_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TEIF8	HTIF8	TCIF8	GIF8	TEIF7	HTIF7	TCIF7	GIF7	TEIF6	HTIF6	TCIF6	GIF6	TEIF5	HTIF5	TCIF5	GIF5
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TEIF4	HTIF4	TCIF4	GIF4	TEIF3	HTIF3	TCIF3	GIF3	TEIF2	HTIF2	TCIF2	GIF2	TEIF1	HTIF1	TCIF1	GIF1
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31, 27, 23, 19, 15, 11, 7, 3 **TEIFx**: Channel x transfer error flag (x = 1..8)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the BDMA\_IFCR register.

- 0: No transfer error (TE) on channel x
- 1: A transfer error (TE) occurred on channel x

Bits 30, 26, 22, 18, 14, 10, 6, 2 **HTIFx**: Channel x half transfer flag (x = 1..8)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the BDMA\_IFCR register.

- 0: No half transfer (HT) event on channel x
- 1: A half transfer (HT) event occurred on channel x

Bits 29, 25, 21, 17, 13, 9, 5, 1 **TCIFx**: Channel x transfer complete flag (x = 1..8)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the BDMA\_IFCR register.

- 0: No transfer complete (TC) event on channel x
- 1: A transfer complete (TC) event occurred on channel x

Bits 28, 24, 20, 16, 12, 8, 4, 0 **GIFx**: Channel x global interrupt flag (x = 1..8)  
 This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the BDMA\_IFCR register.

- 0: No TE, HT or TC event on channel x
- 1: A TE, HT or TC event occurred on channel x

### 16.4.2 DMA interrupt flag clear register (BDMA\_IFCR)

Address offset: 0x04

Reset value: 0x0000 0000

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31, 27, 23, 19, **CTEIFx**: Channel x transfer error clear (x = 1..8)  
 15, 11, 7, 3 This bit is set by software.  
 0: No effect  
 1: Clears the corresponding TEIF flag in the BDMA\_ISR register

Bits 30, 26, 22, 18, **CHTIFx**: Channel x half transfer clear (x = 1..8)  
 14, 10, 6, 2 This bit is set by software.  
 0: No effect  
 1: Clears the corresponding HTIF flag in the BDMA\_ISR register

Bits 29, 25, 21, 17, **CTCIFx**: Channel x transfer complete clear (x = 1..8)  
 13, 9, 5, 1 This bit is set by software.  
 0: No effect  
 1: Clears the corresponding TCIF flag in the BDMA\_ISR register

Bits 28, 24, 20, 16, **CGIFx**: Channel x global interrupt clear (x = 1..8)  
 12, 8, 4, 0 This bit is set by software.  
 0: No effect  
 1: Clears the GIF, TEIF, HTIF and TCIF flags in the BDMA\_ISR register

**16.4.3 DMA channel x configuration register (BDMA\_CCRx)  
(x = 1..8, where x = channel number)**

Address offset: 0x08 + 0d20 × (channel number – 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **MEM2MEM**: Memory to memory mode

This bit is set and cleared by software.

0: Memory to memory mode disabled

1: Memory to memory mode enabled

Bits 13:12 **PL[1:0]**: Channel priority level

These bits are set and cleared by software.

00: Low

01: Medium

10: High

11: Very high

Bits 11:10 **MSIZE[1:0]**: Memory size

These bits are set and cleared by software.

00: 8-bits

01: 16-bits

10: 32-bits

11: Reserved

Bits 9:8 **PSIZE[1:0]**: Peripheral size

These bits are set and cleared by software.

00: 8-bits

01: 16-bits

10: 32-bits

11: Reserved

Bit 7 **MINC**: Memory increment mode

This bit is set and cleared by software.

0: Memory increment mode disabled

1: Memory increment mode enabled

Bit 6 **PINC**: Peripheral increment mode

This bit is set and cleared by software.

0: Peripheral increment mode disabled

1: Peripheral increment mode enabled

- Bit 5 **CIRC**: Circular mode  
This bit is set and cleared by software.  
0: Circular mode disabled  
1: Circular mode enabled
- Bit 4 **DIR**: Data transfer direction  
This bit is set and cleared by software.  
0: Read from peripheral  
1: Read from memory
- Bit 3 **TEIE**: Transfer error interrupt enable  
This bit is set and cleared by software.  
0: TE interrupt disabled  
1: TE interrupt enabled
- Bit 2 **HTIE**: Half transfer interrupt enable  
This bit is set and cleared by software.  
0: HT interrupt disabled  
1: HT interrupt enabled
- Bit 1 **TCIE**: Transfer complete interrupt enable  
This bit is set and cleared by software.  
0: TC interrupt disabled  
1: TC interrupt enabled
- Bit 0 **EN**: Channel enable  
This bit is set and cleared by software.  
0: Channel disabled  
1: Channel enabled

**16.4.4 DMA channel x number of data register (BDMA\_CNDTRx) (x = 1..8, where x = channel number)**

Address offset: 0x0C + 0d20 × (channel number – 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: Number of data to transfer

Number of data to be transferred (0 up to 65535). This register can only be written when the channel is disabled. Once the channel is enabled, this register is read-only, indicating the remaining bytes to be transmitted. This register decrements after each DMA transfer.

Once the transfer is completed, this register can either stay at zero or be reloaded automatically by the value previously programmed if the channel is configured in circular mode.

If this register is zero, no transaction can be served whether the channel is enabled or not.

**16.4.5 DMA channel x peripheral address register (BDMA\_CPARx) (x = 1..8, where x = channel number)**

Address offset: 0x10 + 0d20 × (channel number – 1)

Reset value: 0x0000 0000

This register must *not* be written when the channel is enabled.

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:0 **PA[31:0]**: Peripheral address

Base address of the peripheral data register from/to which the data will be read/written.

When PSIZE is 01 (16-bit), the PA[0] bit is ignored. Access is automatically aligned to a half-word address.

When PSIZE is 10 (32-bit), PA[1:0] are ignored. Access is automatically aligned to a word address.

**16.4.6 DMA channel x memory address register (BDMA\_CMARx) (x = 1..8, where x = channel number)**

Address offset: 0x14 + 0d20 × (channel number – 1)

Reset value: 0x0000 0000

This register must *not* be written when the channel is enabled.

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 17 DMA request multiplexer (DMAMUX)

### 17.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until it is served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is de-asserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controllers of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in [Section 17.3.1](#).

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend on the product implementation, they are detailed in [Section 17.6](#).

### 17.2 DMAMUX main features

- Up to 16-channel programmable DMA request line multiplexer output
- Up to 8-channel DMA request generator
- Up to 32 trigger inputs to DMA request generator
- Up to 16 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - Up to 107 input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining

## 17.3 DMAMUX implementation

### 17.3.1 DMAMUX1 and DMAMUX2 instantiation

The product integrates two instances of DMA request multiplexer:

- DMAMUX1 for DMA1 and DMA2 (D2 domain)
- DMAMUX2 for BDMA (D3 domain)

DMAMUX1 and DMAMUX2 are instantiated with the hardware configuration parameters listed in the following table.

**Table 109. DMAMUX1 and DMAMUX2 instantiation**

Feature	DMAMUX1	DMAMUX2
Number of DMAMUX output request channels	16	8
Number of DMAMUX request generator channels	8	8
Number of DMAMUX request trigger inputs	8	32
Number of DMAMUX synchronization inputs	8	16
Number of DMAMUX peripheral request inputs	107	12

### 17.3.2 DMAMUX1 mapping

The mapping of resources to DMAMUX1 is hardwired.

DMAMUX1 is used with the DMA1 and DMA2 in D2 domain:

- DMAMUX1 channels 0 to 7 are connected to DMA1 channels 0 to 7
- DMAMUX1 channels 8 to 15 are connected to DMA2 channels 0 to 7

**Table 110. DMAMUX1: assignment of multiplexer inputs to resources**

DMA request MUX input	Resource	DMA request MUX input	Resource	DMA request MUX input	Resource
1	dmamux1_req_gen0	40	SPI2_TX	79	UART7_RX

## 17.4 DMAMUX functional description

### 17.4.1 DMAMUX block diagram

Figure 75 shows the DMAMUX block diagram.

Figure 75. DMAMUX block diagram

DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux\_reqx) from peripherals (dmamux\_req\_inx) and from channels of the DMAMUX request generator sub-block (dmamux\_req\_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux\_req\_outx)
- Internal or external signals to DMA request trigger inputs (dmamux\_trgx)
- Internal or external signals to synchronization inputs (dmamux\_syncx)

## 17.4.2 DMAMUX signals

Table 116 lists DMAMUX signals.

**Table 116. DMAMUX signals**

Signal name	Description
dmamux_hclk	DMAMUX AHB clock
dmamux_req_inx	DMAMUX DMA request line inputs from peripherals
dmamux_trgx	DMAMUX DMA request triggers inputs (to request generator sub-block)
dmamux_req_genx	DMAMUX request generator sub-block channels outputs
dmamux_reqx	DMAMUX request multiplexer sub-block inputs (from peripheral requests and request generator channels)
dmamux_syncx	DMAMUX synchronization inputs (to request multiplexer sub-block)
dmamux_req_outx	DMAMUX requests outputs (to DMA controllers)
dmamux_evtx	DMAMUX events outputs
dmamux_ovr_it	DMAMUX overrun interrupts

## 17.4.3 DMAMUX channels

A DMAMUX channel is a DMAMUX request multiplexer channel that may include, depending on the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to one single channel of DMA controller(s).

### Channel configuration procedure

The following sequence should be followed to configure both a DMAMUX x channel and the related DMA channel y:

1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.

## 17.4.4 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced either from the peripherals or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the 8-bit DMAREQ\_ID field in the DMAMUX\_CxCR register.

*Note:* The null value in the field `DMAREQ_ID` corresponds to no DMA request line selected. The same non-null `DMA_REQ_ID` value shall not be programmed to different `x` and `y` DMAMUX request multiplexer channels (via `DMAMUX_CxCR` and `DMAMUX_CyCR`). It is not allowed to configure a same non-null `DMAREQ_ID` to two different channels of the DMAMUX request line multiplexer.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

### Synchronization mode and channel event generation

Each DMAMUX request line multiplexer channel `x` can be individually synchronized by setting the synchronization enable (SE) bit in the `DMAMUX_CxCR` register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the 5-bit `SYNC_ID` field in the `DMAMUX_CxCR` register of a given channel `x`.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once is detected a programmable rising/falling edge on the selected input synchronization signal, via the `SPOL[1:0]` field of the `DMAMUX_CxCR` register.

Additionally, there is a programmable DMA request counter, internally to the DMAMUX request multiplexer, which may be used for the channel request output generation and also possibly for an event generation. An event generation on the channel `x` output is enabled through the EGE bit (event generation enable) of the `DMAMUX_CxCR` register.

As shown in the two next figures, upon the detected edge of the synchronization input, the selected input DMA request line is connected to the DMAMUX multiplexer channel `x` output. From this point on, each served DMA request (for example when the request signal is de-asserted) on the selected DMAMUX request line decrements the DMA request counter. At its underrun, the DMA request counter is automatically loaded with the value in `NBREQ` field of the `DMAMUX_CxCR` register and the input DMA request line is disconnected from the multiplexer channel `x` output.

Thus, the number of DMA requests transferred to the multiplexer channel `x` output following a detected synchronization event, is equal to the value in `NBREQ` field, plus one.

*Note:* The `NBREQ` field value shall only be written by software when both synchronization enable bit SE and event generation enable EGE bit of the corresponding multiplexer channel `x` are disabled.

If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed `NBREQ` field.

Figure 76. Synchronization mode of the DMAMUX request line multiplexer channel

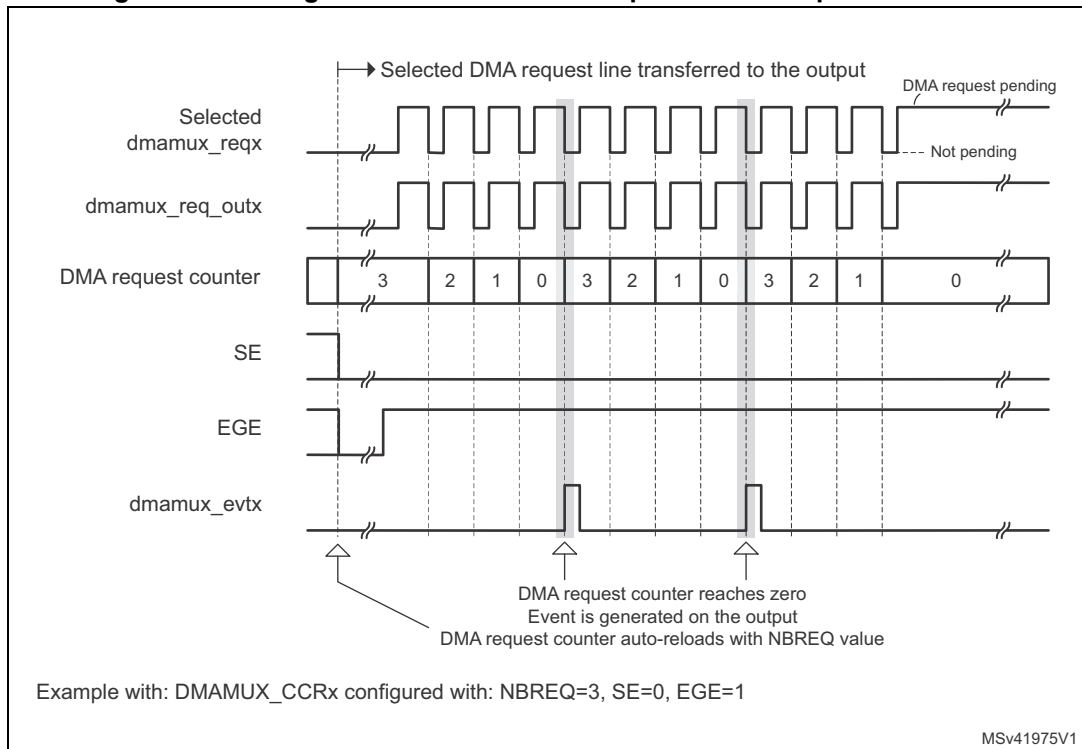

Figure 77. Event generation of the DMA request line multiplexer channel

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX\_CxCR register, the synchronization events are masked during three AHB clock cycles.

### Synchronization overrun and interrupt

If a new synchronization event occurs while the value of the DMA request counter is lower than the programmed NBREQ field value of the multiplexer channel x, the synchronization overrun flag bit SOFx is set in the DMAMUX\_CSR status register.

*Note:* The request multiplexer channel x synchronization shall be disabled (DMAMUX\_CxCR.SE=0) at the completion of the usage of the related channel of the DMA controller. Else, upon a new detected synchronization event, there will be a synchronization overrun due to the absence of a DMA acknowledge (a.k.a. no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX\_CFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX\_CxCR register.

## 17.4.5 DMAMUX request generator

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX\_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG\_ID (trigger signal ID) field in the corresponding DMAMUX\_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX\_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each served DMA request (i.e. when the request signal is deasserted) decrements a built-in DMA request counter, internally to the DMAMUX request generator. At its underrun, the DMA request counter is automatically loaded with the value in GNBREQ field of the corresponding DMAMUX\_RGxCR register and the request generator channel stops generating DMA requests.

Thus, the number of DMA requests generated after the trigger event is GNBREQ+1.

The DMA request counter is kept at GNBREQ field value as long as the corresponding channel is disabled i.e. the DMAMUX\_RGxCR.GE bit is low.

*Note:* The GNBREQ field value shall only be written by software when the enable GE bit of the corresponding generator channel x is disabled.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX\_RGxCR register, the trigger events are masked during three AHB clock cycles.

**Trigger overrun and interrupt**

If a new DMA request trigger event occurs while the value of the DMAMUX request generator counter is lower than the programmed GNBREQ field value of the corresponding request generator channel x, and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the status DMAMUX\_RGSR register.

*Note:* The request generator channel x shall be disabled (DMAMUX\_RGxCR.GE=0) at the completion of the usage of the related channel of the DMA controller. Else, upon a new detected trigger event, there will be a trigger overrun due to the absence of an acknowledge (a.k.a. no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX\_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX\_RGxCR register.

**17.5 DMAMUX interrupts**

An interrupt can be generated upon:

- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel individual interrupt enable, status and clear flag register bits are available.

**Table 117. DMAMUX interrupts**

Interrupt signal	Interrupt event	Event flag	Clear bit	Enable bit
dmamuxovr_it	Synchronization event overrun on channel x of the DMAMUX request line multiplexer	SOFx	CSOFx	SOIE
	Trigger event overrun on channel x of the DMAMUX request generator	OFx	COFx	OIE

## 17.6 DMAMUX registers

Refer to the table containing register boundary addresses for the DMAMUX1 and DMAMUX2 base address.

DMAMUX registers may be accessed per (8-bit) byte, (16-bit) half-word, or (32-bit) word. The address shall be aligned with the data size.

### 17.6.1 DMAMUX1 request line multiplexer channel x configuration register (DMAMUX1\_CxCR)

Address offset: 0x04 \* x (x = 0 to 15)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SYNC_ID[4:0]				NBREQ[4:0]				SPOL[1:0]		SE		
			rw				rw				rw		rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	EGE	SOIE	DMAREQ_ID[7:0]							
						rw	rw	rw							

Bits 31:29 Reserved, must be kept at reset value

Bits 28:24 **SYNC\_ID[4:0]**: Synchronization identification

Selects the synchronization input (see [Table 112: DMAMUX1: assignment of synchronization inputs to resources](#)).

Bits 23:19 **NBREQ[4:0]**: Number of DMA requests minus 1 to forward

Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.

This field shall only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]**: Synchronization polarity

Defines the edge polarity of the selected synchronization input:

00: no event, i.e. no synchronization nor detection.

01: rising edge

10: falling edge

11: rising and falling edge

Bit 16 **SE**: Synchronization enable

0: synchronization disabled

1: synchronization enabled

Bits 15:10 Reserved, must be kept at reset value

Bit 9 **EGE**: Event generation enable

0: event generation disabled

1: event generation enabled

Bit 8 **SOIE**: Synchronization overrun interrupt enable

0: interrupt disabled

1: interrupt enabled

Bits 7:0 **DMAREQ\_ID[7:0]**: DMA request identification

Selects the input DMA request. C.f. the DMAMUX table about assignments of multiplexer inputs to resources.

### 17.6.2 DMAMUX2 request line multiplexer channel x configuration register (DMAMUX2\_CxCR)

Address offset: 0x04 \* x, where x = 0 to 7

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SYNC_ID[4:0]				NBREQ[4:0]				SPOL[1:0]		SE		
			rw				rw				rw		rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	EGE	SOIE	DMAREQ_ID[7:0]							
						rw	rw	rw							

Bits 31:29 Reserved, must be kept at reset value

Bits 28:24 **SYNC\_ID[4:0]**: Synchronization identification

Selects the synchronization input. (C.f. table: DMAMUX- assignments of synchronization inputs to resources)

Bits 23:19 **NBREQ[4:0]**: Number of DMA requests minus 1 to forward

Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated. This field shall only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]**: Synchronization polarity

Defines the edge polarity of the selected synchronization input:

00: no event. I.e. None synchronization nor detection.

01: rising edge

10: falling edge

11: rising and falling edge

Bit 16 **SE**: Synchronization enable

0: synchronization disabled

1: synchronization enabled

Bits 15:10 Reserved, must be kept at reset value

Bit 9 **EGE**: Event generation enable

0: event generation disabled

1: event generation enabled

Bit 8 **SOIE**: Synchronization overrun interrupt enable

0: interrupt disabled

1: interrupt enabled

Bits 7:0 **DMAREQ\_ID[7:0]**: DMA request identification

Selects the input DMA request. C.f. the DMAMUX table about assignments of multiplexer inputs to resources.

### 17.6.3 DMAMUX1 request line multiplexer interrupt channel status register (DMAMUX1\_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SOF15	SOF14	SOF13	SOF12	SOF11	SOF10	SOF9	SOF8	SOF7	SOF6	SOF5	SOF4	SOF3	SOF2	SOF1	SOF0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **SOF[15:0]**: Synchronization overrun event flag

The flag is set when a synchronization event occurs on a DMA request line multiplexer channel x, while the DMA request counter value is lower than NBREQ.

The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX\_CFR register.

For DMAMUX2\_CFR bits 15:8 are reserved.

### 17.6.4 DMAMUX2 request line multiplexer interrupt channel status register (DMAMUX2\_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

This register shall be accessed at bit level by a non-secure or secure read, according to the secure mode of the considered DMAMUX2 request line multiplexer channel x, depending on the secure control bit of the connected DMA controller channel y, and considering that the DMAMUX2 x channel output is connected to the y channel of the DMA (refer to the DMAMUX2 mapping implementation section).

This register shall be accessed at bit level by an unprivileged or privileged read, according to the privileged mode of the considered DMAMUX2 request line multiplexer channel x, depending on the privileged control bit of the connected DMA controller channel y, and considering that the DMAMUX2 x channel output is connected to the y channel of the DMA (refer to the DMAMUX2 mapping implementation section).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SOF7	SOF6	SOF5	SOF4	SOF3	SOF2	SOF1	SOF0
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **SOF[7:0]**: Synchronization overrun event flag

The flag is set when a synchronization event occurs on a DMA request line multiplexer channel x, while the DMA request counter value is lower than NBREQ.

The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX2\_CFR register.

### 17.6.5 DMAMUX1 request line multiplexer interrupt clear flag register (DMAMUX1\_CFR)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSOF1 5	CSOF1 4	CSOF1 3	CSOF1 2	CSOF11	CSOF1 0	CSOF9	CSOF8	CSOF7	CSOF6	CSOF5	CSOF4	CSOF3	CSOF2	CSOF1	CSOF0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **CSOF[15:0]**: Clear synchronization overrun event flag

Writing 1 in each bit clears the corresponding overrun flag SOF<sub>x</sub> in the DMAMUX\_CSR register.

### 17.6.6 DMAMUX2 request line multiplexer interrupt clear flag register (DMAMUX2\_CFR)

Address offset: 0x084

Reset value: 0x0000 0000

This register shall be written at bit level by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel x, depending on the secure control bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

This register shall be written at bit level by an unprivileged or privileged write, according to the privileged mode of the considered DMAMUX request line multiplexer channel x, depending on the privileged control bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **CSOF[7:0]**: Clear synchronization overrun event flag

Writing 1 in each bit clears the corresponding overrun flag SOF<sub>x</sub> in the DMAMUX2\_CSR register.

### 17.6.7 DMAMUX1 request generator channel x configuration register (DMAMUX1\_RGxCR)

Address offset:  $0x100 + 0x04 * (x-0)$  ( $x = 0$  to  $7$ )

Reset value:  $0x0000\ 0000$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GNBREQ[4:0]				GPOL[1:0]		GE	
								rw				rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	OIE	Res.	Res.	Res.	SIG_ID[4:0]				
							rw				rw				

Bits 31:24 Reserved, must be kept at reset value

Bits 23:19 **GNBREQ[4:0]**: Number of DMA requests to be generated (minus 1)

Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is  $GNBREQ+1$ .

*Note: This field shall only be written when GE bit is disabled.*

Bits 18:17 **GPOL[1:0]**: DMA request generator trigger polarity

Defines the edge polarity of the selected trigger input  
 00: no event. I.e. none trigger detection nor generation.  
 01: rising edge  
 10: falling edge  
 11: rising and falling edge

Bit 16 **GE**: DMA request generator channel x enable  
 0: DMA request generator channel x disabled  
 1: DMA request generator channel x enabled

Bits 15:9 Reserved, must be kept at reset value

Bit 8 **OIE**: Trigger overrun interrupt enable  
 0: interrupt on a trigger overrun event occurrence is disabled  
 1: interrupt on a trigger overrun event occurrence is enabled

Bits 7:5 Reserved, must be kept at reset value

Bits 4:0 **SIG\_ID[4:0]**: Signal identification  
 Selects the DMA request trigger input used for the channel x of the DMA request generator

### 17.6.8 DMAMUX2 request generator channel x configuration register (DMAMUX2\_RGxCR)

Address offset:  $0x100 + 0x04 * (x-0)$  ( $x = 0$  to  $7$ )

Reset value:  $0x0000\ 0000$

This register shall be written by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel y it is assigned to, and considering that the DMAMUX request generator x channel output is selected by the y channel of the DMAMUX request line channel (see DMAMUX2\_CyCR.DMAREQ\_ID[7:0] and the DMAMUX mapping implementation section).

This register shall be written by an unprivileged or privileged write, according to the privileged mode of the considered DMAMUX request line multiplexer channel y it is assigned to, and considering that the DMAMUX request generator x channel output is selected by the y channel of the DMAMUX request line channel (see DMAMUX2\_CyCR.DMAREQ\_ID[7:0] and the DMAMUX mapping implementation section).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GNBREQ[4:0]				GPOL[1:0]		GE	
								rw				rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	OIE	Res.	Res.	Res.	SIG_ID[4:0]				
							rw				rw				

Bits 31:24 Reserved, must be kept at reset value

Bits 23:19 **GNBREQ[4:0]**: Number of DMA requests to be generated (minus 1)

Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is GNBREQ+1.

*Note: This field shall only be written when GE bit is disabled.*

Bits 18:17 **GPOL[1:0]**: DMA request generator trigger polarity

Defines the edge polarity of the selected trigger input

00: no event. I.e. none trigger detection nor generation.

01: rising edge

10: falling edge

11: rising and falling edge

Bit 16 **GE**: DMA request generator channel x enable

0: DMA request generator channel x disabled

1: DMA request generator channel x enabled

Bits 15:9 Reserved, must be kept at reset value

Bit 8 **OIE**: Trigger overrun interrupt enable

0: interrupt on a trigger overrun event occurrence is disabled

1: interrupt on a trigger overrun event occurrence is enabled

Bits 7:5 Reserved, must be kept at reset value

Bits 4:0 **SIG\_ID[4:0]**: Signal identification

Selects the DMA request trigger input used for the channel x of the DMA request generator

### 17.6.9 DMAMUX1 request generator interrupt status register (DMAMUX1\_RGSR)

Address offset: 0x140

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OF7	OF6	OF5	OF4	OF3	OF2	OF1	OF0
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **OF[7:0]**: Trigger overrun event flag

The flag is set when a trigger event occurs on DMA request generator channel x, while the DMA request generator counter value is lower than GNBREQ.

The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX\_RGCFR register.

### 17.6.10 DMAMUX2 request generator interrupt status register (DMAMUX2\_RGSR)

Address offset: 0x140

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **OF[7:0]**: Trigger overrun event flag

The flag is set when a trigger event occurs on DMA request generator channel x, while the DMA request generator counter value is lower than GNBREQ.

The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX2\_RGCFR register.

**17.6.11 DMAMUX1 request generator interrupt clear flag register (DMAMUX1\_RGCFR)**

Address offset: 0x144

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

2. For DMAMUX2, the bits 15:8 are reserved.

## 18 Chrom-Art Accelerator™ controller (DMA2D)

### 18.1 DMA2D introduction

The Chrom-Art Accelerator™ (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format.

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

## 18.2 DMA2D main features

The main DMA2D features are:

- Single AXI master bus architecture.
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit).
- User programmable working area size
- User programmable offset for sources and destination areas
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AXI bandwidth
- 4 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, and memory-to-memory with pixel format conversion and blending
- Area filling with a fixed color
- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

## 18.3 DMA2D functional description

### 18.3.1 General description

The DMA2D controller performs direct memory transfer. As an AXI master, it can take the control of the AXI bus matrix to initiate AXI transactions.

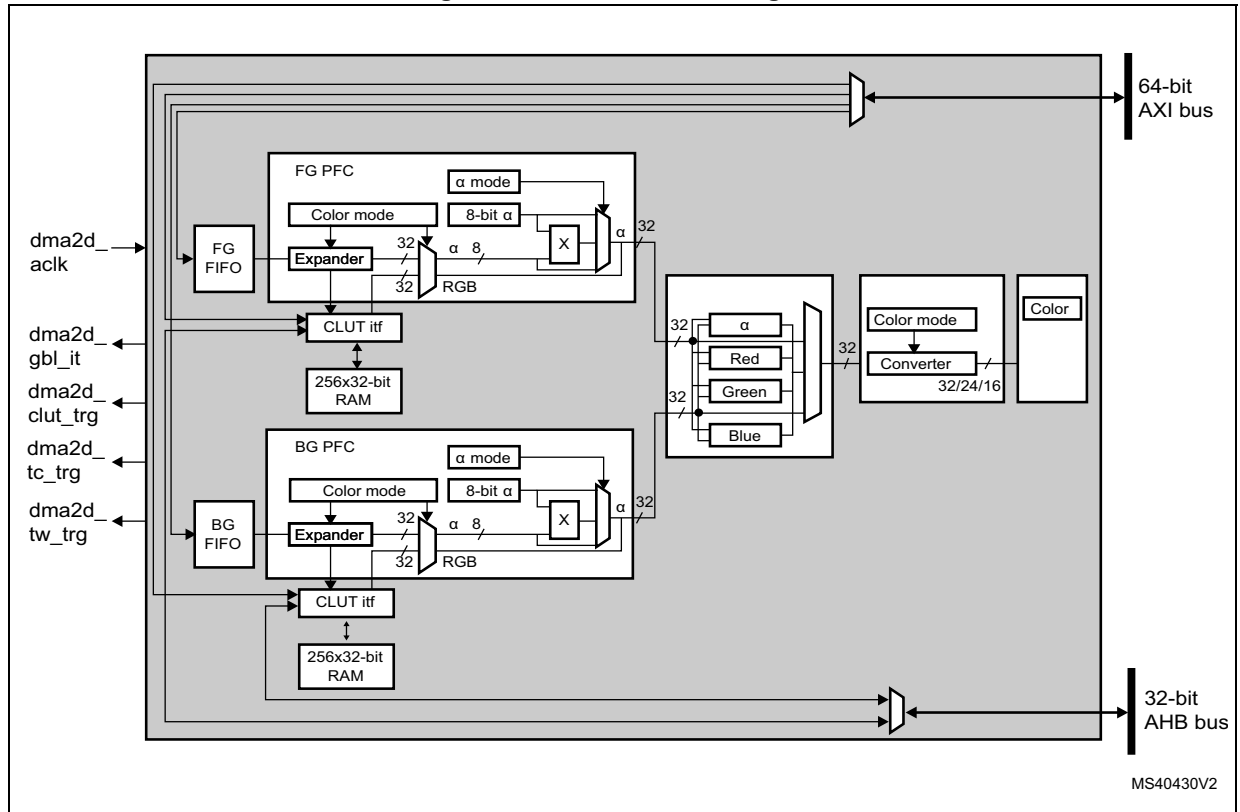

The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with Pixel Format Conversion
- Memory-to-memory with Pixel Format Conversion and Blending

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in *Figure 78: DMA2D block diagram*.

**Figure 78. DMA2D block diagram**

## 18.4 DMA2D pins and internal signals

*Table 119* lists the DMA2D internal signals.

**Table 119. DMA2D internal input/output signals**

Signal name	Signal type	Description
dma2d_aclk	Digital input	32-bit AXI bus clock
dma2d_gbl_it	Digital output	DMA2D global interrupt
dma2d_clut_trg	Digital output	CLUT transfer complete (to MDMA)
dma2d_tc_trg	Digital output	Transfer complete (to MDMA)
dma2d_tw_trg	Digital output	Transfer watermark (to MDMA)

### 18.4.1 DMA2D control

The DMA2D controller is configured through the DMA2D Control Register (DMA2D\_CR) which allows selecting:

The user application can perform the following operations:

- Select the operating mode
- Enable/disable the DMA2D interrupt
- Start/suspend/abort ongoing data transfers

### 18.4.2 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through a set of control registers:

- DMA2D foreground memory address register (DMA2D\_FGMAR)
- DMA2D foreground offset register (DMA2D\_FGOR)
- DMA2D background memory address register (DMA2D\_BGMAR)
- DMA2D background offset register (DMA2D\_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

### 18.4.3 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D\_FGPFCCR and DMA2D\_BGPFCCR, respectively.

The supported input formats are given in [Table 120: Supported color mode in input](#).

**Table 120. Supported color mode in input**

CM[3:0]	Color mode
0000	ARGB8888
0001	RGB888
0010	RGB565
0011	ARGB1555
0100	ARGB4444

Table 120. Supported color mode in input

CM[3:0]	Color mode
0101	L8
0110	AL44
0111	AL88
1000	L4
1001	A8
1010	A4
1011	YCbCr (only for foreground)

The color format are coded as follows:

- Alpha value field: transparency  
0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance  
This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode, then the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode, a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D\_FGCOLR for foreground pixels and in the DMA2D\_BGCOLOR register for background pixels.

The order of the fields in the system memory is defined in [Table 121: Data order in memory](#).

Table 121. Data order in memory

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A <sub>0</sub> [7:0]	R <sub>0</sub> [7:0]	G <sub>0</sub> [7:0]	B <sub>0</sub> [7:0]
RGB888	B <sub>1</sub> [7:0]	R <sub>0</sub> [7:0]	G <sub>0</sub> [7:0]	B <sub>0</sub> [7:0]
	G <sub>2</sub> [7:0]	B <sub>2</sub> [7:0]	R <sub>1</sub> [7:0]	G <sub>1</sub> [7:0]
	R <sub>3</sub> [7:0]	G <sub>3</sub> [7:0]	B <sub>3</sub> [7:0]	R <sub>2</sub> [7:0]
RGB565	R <sub>1</sub> [4:0]G <sub>1</sub> [5:3]	G <sub>1</sub> [2:0]B <sub>1</sub> [4:0]	R <sub>0</sub> [4:0]G <sub>0</sub> [5:3]	G <sub>0</sub> [2:0]B <sub>0</sub> [4:0]
ARGB1555	A <sub>1</sub> [0]R <sub>1</sub> [4:0]G <sub>1</sub> [4:3]	G <sub>1</sub> [2:0]B <sub>1</sub> [4:0]	A <sub>0</sub> [0]R <sub>0</sub> [4:0]G <sub>0</sub> [4:3]	G <sub>0</sub> [2:0]B <sub>0</sub> [4:0]
ARGB4444	A <sub>1</sub> [3:0]R <sub>1</sub> [3:0]	G <sub>1</sub> [3:0]B <sub>1</sub> [3:0]	A <sub>0</sub> [3:0]R <sub>0</sub> [3:0]	G <sub>0</sub> [3:0]B <sub>0</sub> [3:0]
L8	L <sub>3</sub> [7:0]	L <sub>2</sub> [7:0]	L <sub>1</sub> [7:0]	L <sub>0</sub> [7:0]
AL44	A <sub>3</sub> [3:0]L <sub>3</sub> [3:0]	A <sub>2</sub> [3:0]L <sub>2</sub> [3:0]	A <sub>1</sub> [3:0]L <sub>1</sub> [3:0]	A <sub>0</sub> [3:0]L <sub>0</sub> [3:0]
AL88	A <sub>1</sub> [7:0]	L <sub>1</sub> [7:0]	A <sub>0</sub> [7:0]	L <sub>0</sub> [7:0]
L4	L <sub>7</sub> [3:0]L <sub>6</sub> [3:0]	L <sub>5</sub> [3:0]L <sub>4</sub> [3:0]	L <sub>3</sub> [3:0]L <sub>2</sub> [3:0]	L <sub>1</sub> [3:0]L <sub>0</sub> [3:0]
A8	A <sub>3</sub> [7:0]	A <sub>2</sub> [7:0]	A <sub>1</sub> [7:0]	A <sub>0</sub> [7:0]
A4	A <sub>7</sub> [3:0]A <sub>6</sub> [3:0]	A <sub>5</sub> [3:0]A <sub>4</sub> [3:0]	A <sub>3</sub> [3:0]A <sub>2</sub> [3:0]	A <sub>1</sub> [3:0]A <sub>0</sub> [3:0]

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to the AM[1:0] field of the DMA2D\_FGPFCCR/DMA2D\_BGPFCCR registers as shown in [Table 122: Alpha mode configuration](#).

The alpha channel can be:

- kept as it is (no modification),
- replaced by the ALPHA[7:0] value of DMA2D\_FGPFCCR/DMA2D\_BGPFCCR,
- or replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D\_FGPFCCR/DMA2D\_BGPFCCR divided by 255.

Table 122. Alpha mode configuration

AM[1:0]	Alpha mode
00	No modification
01	Replaced by value in DMA2D_xxPFCCR
10	Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255
11	Reserved

*Note:* To support the alternate format, the incoming alpha value can be inverted setting the AI bit of the DMA2D\_FGPFCCR/DMA2D\_BGPFCCR registers. This applies also to the Alpha value stored in the DMA2D\_FGPFCCR/DMA2D\_BGPFCCR and in the CLUT.

The R and B fields can also be swapped setting the RBS bit of the DMA2D\_FGPFCCR/DMA2D\_BGPFCCR registers. This applies also to the RGB order used in the CLUT and in the DMA2D\_FGCOLOR/DMA2D\_BGCOLOR registers.

### 18.4.4 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AXI master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading

The following sequence should be followed to load the CLUT:

- a) Program the CLUT address into the DMA2D\_FGCMAR register (foreground CLUT) or DMA2D\_BGCMAR register (background CLUT)
- b) Program the CLUT size in the CS[7:0] field of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT).
- c) Set the START bit of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE is set to '1' in DMA2D\_CR.

- Manual loading

The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through the CCM bit of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT) as shown in [Table 123: Supported CLUT color mode](#).

**Table 123. Supported CLUT color mode**

CCM	CLUT color mode
0	32-bit ARGB8888
1	24-bit RGB888

The way the CLUT data are organized in the system memory is specified in [Table 124: CLUT data order in memory](#).

**Table 124. CLUT data order in memory**

CLUT Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A <sub>0</sub> [7:0]	R <sub>0</sub> [7:0]	G <sub>0</sub> [7:0]	B <sub>0</sub> [7:0]
RGB888	B <sub>1</sub> [7:0]	R <sub>0</sub> [7:0]	G <sub>0</sub> [7:0]	B <sub>0</sub> [7:0]
	G <sub>2</sub> [7:0]	B <sub>2</sub> [7:0]	R <sub>1</sub> [7:0]	G <sub>1</sub> [7:0]
	R <sub>3</sub> [7:0]	G <sub>3</sub> [7:0]	B <sub>3</sub> [7:0]	R <sub>2</sub> [7:0]

### 18.4.5 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

*Division is rounded to the nearest lower integer*

No configuration register is required by the blender. The blender usage depends on the DMA2D operating mode defined in MODE[1:0] field of the DMA2D\_CR register.

### 18.4.6 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined in the CM[2:0] field of the DMA2D output pixel format converter configuration register (DMA2D\_OPFCCR).

The supported output formats are given in [Table 125: Supported color mode in output](#)

**Table 125. Supported color mode in output**

CM[2:0]	Color mode
000	ARGB8888
001	RGB888
010	RGB565
011	ARGB1555
100	ARGB4444

*Note:* To support the alternate format, the calculated alpha value can be inverted setting the AI bit of the DMA2D\_OPFCCR registers. This applies also to the Alpha value used in the DMA2D\_OCOLR.

The R and B fields can also be swapped setting the RBS bit of the DMA2D\_OPFCCR registers. This applies also to the RGB order used in the DMA2D\_OCOLR.

### 18.4.7 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:

- DMA2D output memory address register (DMA2D\_OMAR)
- DMA2D output offset register (DMA2D\_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in the DMA2D output color register (DMA2D\_OCOLR) which contains a fixed 32-bit, 24-bit or 16-bit value. The format is selected by the CM[2:0] field of the DMA2D\_OPFCCR register.

The data are stored into the memory in the order defined in [Table 126: Data order in memory](#)

**Table 126. Data order in memory**

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A <sub>0</sub> [7:0]	R <sub>0</sub> [7:0]	G <sub>0</sub> [7:0]	B <sub>0</sub> [7:0]
RGB888	B <sub>1</sub> [7:0]	R <sub>0</sub> [7:0]	G <sub>0</sub> [7:0]	B <sub>0</sub> [7:0]
	G <sub>2</sub> [7:0]	B <sub>2</sub> [7:0]	R <sub>1</sub> [7:0]	G <sub>1</sub> [7:0]
	R <sub>3</sub> [7:0]	G <sub>3</sub> [7:0]	B <sub>3</sub> [7:0]	R <sub>2</sub> [7:0]
RGB565	R <sub>1</sub> [4:0]G <sub>1</sub> [5:3]	G <sub>1</sub> [2:0]B <sub>1</sub> [4:0]	R <sub>0</sub> [4:0]G <sub>0</sub> [5:3]	G <sub>0</sub> [2:0]B <sub>0</sub> [4:0]
ARGB1555	A <sub>1</sub> [0]R <sub>1</sub> [4:0]G <sub>1</sub> [4:3]	G <sub>1</sub> [2:0]B <sub>1</sub> [4:0]	A <sub>0</sub> [0]R <sub>0</sub> [4:0]G <sub>0</sub> [4:3]	G <sub>0</sub> [2:0]B <sub>0</sub> [4:0]
ARGB4444	A <sub>1</sub> [3:0]R <sub>1</sub> [3:0]	G <sub>1</sub> [3:0]B <sub>1</sub> [3:0]	A <sub>0</sub> [3:0]R <sub>0</sub> [3:0]	G <sub>0</sub> [3:0]B <sub>0</sub> [3:0]

The RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

#### 18.4.8 DMA2D AXI master port timer

An 8-bit timer is embedded into the AXI master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AXI clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and the dead time value are configured through the AXI master port timer configuration register (DMA2D\_AMPTCR).

#### 18.4.9 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to 4 steps:

1. Data loading from the memory location pointed by the DMA2D\_FGMAR register and pixel format conversion as defined in DMA2D\_FGCR.
2. Data loading from a memory location pointed by the DMA2D\_BGMAR register and pixel format conversion as defined in DMA2D\_BGCR.
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values.
4. Pixel format conversion of the resulting pixels according to the DMA2D\_OCR register and programming of the data to the memory location addressed through the DMA2D\_OMAR register.

#### 18.4.10 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the four following modes selected through MODE[1:0] bits of the DMA2D\_CR register:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending

##### Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color.

The color format is set in the DMA2D\_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in the DMA2D\_OCOLR register to the area located at the address pointed by the DMA2D\_OMAR and defined in the DMA2D\_NLR and DMA2D\_OOR.

##### Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D\_FGMAR to the destination memory location pointed by DMA2D\_OMAR.

The color mode programmed in the CM[3:0] bits of the DMA2D\_FGPFCCR register defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by the DMA2D\_NLR and DMA2D\_FGOR registers for the source, and by DMA2D\_NLR and DMA2D\_OOR registers for the destination.

##### Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by the DMA2D\_NLR and DMA2D\_FGOR registers for the source, and by DMA2D\_NLR and DMA2D\_OOR registers for the destination.

Data are fetched from the location defined in the DMA2D\_FGMAR register and processed by the foreground PFC. The original pixel format is configured through the DMA2D\_FGPFCCR register.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into the DMA2D\_FGCMAR.
2. Set the CLUT size in the CS[7:0] bits of the DMA2D\_FGPFCCR register.
3. Set the CLUT format (24 or 32 bits) in the CCM bit of the DMA2D\_FGPFCCR register.
4. Start the CLUT loading by setting the START bit of the DMA2D\_FGPFCCR register.

Once the CLUT loading is complete, the CTCIF flag of the DMA2D\_IFR register is raised, and an interrupt is generated if the CTCIE bit is set in DMA2D\_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in the DMA2D\_FGPFCCR register. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value can be modified according to the AM[1:0] bits of the DMA2D\_FGPFCCR register:

- It can be unchanged.
- It can be replaced by the value defined in the ALPHA[7:0] value of the DMA2D\_FGPFCCR register.
- It can be replaced by the original value multiplied by the ALPHA[7:0] value of the DMA2D\_FGPFCCR register divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by the CM[2:0] field of the DMA2D\_OPFCCR register. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D\_OMAR.

### Memory-to-memory with PFC and blending

In this mode, 2 sources are fetched in the foreground FIFO and background FIFO from the memory locations defined by DMA2D\_FGMAR and DMA2D\_BGMR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended according to the equation below:

$$\text{with } \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

*Division are rounded to the nearest lower integer*

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D\_OMAR.

### Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if the CEIE bit of the DMA2D\_CR is set.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits of DMA2D\_FGCMAR not aligned with CCM of DMA2D\_FGPFCCR.
- Background CLUT automatic loading: MA of DMA2D\_BGCMAR not aligned with CCM of DMA2D\_BGPFCCR
- Memory transfer (except in register-to-memory mode): MA of DMA2D\_FGMAR not aligned with CM of DMA2D\_FGPFCCR
- Memory transfer (except in register-to-memory mode): CM in DMA2D\_FGPFCCR are invalid
- Memory transfer (except in register-to-memory mode): PL bits of DMA2D\_NLR odd while CM of DMA2D\_FGPFCCR is A4 or L4
- Memory transfer (except in register-to-memory mode): LO bits in DMA2D\_FGOR odd while CM of DMA2D\_FGPFCCR is A4 or L4
- Memory transfer (only in blending mode): MA bits in DMA2D\_BGMAR are not aligned with the CM of DMA2D\_BGPFCCR
- Memory transfer: CM of DMA2D\_BGPFCCR invalid (only in blending mode)
- Memory transfer (only in blending mode): PL bits of DMA2D\_NLR odd while CM of DMA2D\_BGPFCCR is A4 or L4
- Memory transfer (only in blending mode): LO bits of DMA2D\_BGOR odd while CM of DMA2D\_BGPFCCR is A4 or L4
- Memory transfer (except in memory to memory mode): MA bits in DMA2D\_OMAR are not aligned with CM bits in DMA2D\_OPFCCR.
- Memory transfer (except in memory to memory mode): CM bits in DMA2D\_OPFCCR invalid
- Memory transfer: NL bits in DMA2D\_NLR = 0

- Memory transfer: PL bits in DMA2D\_NLR = 0
- YCbCr format: when a CLUT loading starts setting the START bit of the DMA2D\_FGPFCCR.
- YCbCr format: when the memory-to-memory mode is selected.
- YCbCr format: when YCbCr4:4:4 is selected and the sum of the number of pixel (PL) and the line offset LO is not a multiple of 8 pixels.
- YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected and the sum of the number of pixel (PL) and the line offset LO is not a multiple of 16 pixels.

### 18.4.11 YCbCr support

The DMA2D foreground plane can support 8x8 block based YCbCr as output by the JPEG decoder with different chroma sub-sampling factors:

The memory organization follows the standard JFIF rules:

- Each of the three color component must be coded on 8-bit
- Each component must be arranged by blocks of 8x8 (64 bytes) called MCU

Depending of the chroma sub-sampling factor the MCU must be arranged in the memory as described in [Table 127: MCU order in memory](#).

**Table 127. MCU order in memory**

Sub-sampling	@	@ + 64	@ + 128	@+192	@+256	@ + 320
4:4:4	Y <sub>1</sub>	Cb <sub>1</sub>	Cr <sub>1</sub>	Y <sub>2</sub>	Cb <sub>2</sub>	Cr <sub>2</sub>
4:2:2	Y <sub>1</sub>	Y <sub>2</sub>	Cb <sub>12</sub>	Cr <sub>12</sub>	Y <sub>3</sub>	Y <sub>4</sub>
4:2:0	Y <sub>1</sub>	Y <sub>2</sub>	Y <sub>3</sub>	Y <sub>4</sub>	Cb <sub>1234</sub>	Cr <sub>1234</sub>

The chroma sub-sampling factor is configured through the CSS field of the DMA2D\_FGPFCCR register.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first 2 chroma MCU are loaded in the foreground CLUT. Once the chroma MCU are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

### 18.4.12 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting the START bit of the DMA2D\_CR register. Once the transfer is completed, the START bit is automatically reset and the TCIF flag of the DMA2D\_ISR register is raised. An interrupt can be generated if the TCIE bit of the DMA2D\_CR is set.

The user application can suspend the DMA2D at any time by setting the SUSP bit of the DMA2D\_CR register. The transaction can then be aborted by setting the ABORT bit of the DMA2D\_CR register or can be restarted by resetting the SUSP bit of the DMA2D\_CR register.

The user application can abort at any time an ongoing transaction by setting the ABORT bit of the DMA2D\_CR register. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using their own START bits in the DMA2D\_FGPFCCR and DMA2D\_BGPFCCR registers.

### 18.4.13 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in the LW[15:0] field of the DMA2D\_LWR register.

When the last pixel of this line has been transferred, the TWIF flag of the DMA2D\_ISR register is raised and an interrupt is generated if the TWIE bit of the DMA2D\_CR is set.

### 18.4.14 Error management

Two kind of errors can be triggered:

- AXI master port errors signaled by the TEIF flag of the DMA2D\_ISR register.
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by the CAEIF flag of the DMA2D\_ISR register.

Both flags are associated to their own interrupt enable flag in the DMA2D\_CR register to generate an interrupt if need be (TEIE and CAEIE).

### 18.4.15 AXI dead time

To limit the AXI bandwidth usage, a dead time between two consecutive AXI accesses can be programmed.

This feature can be enabled by setting the EN bit in the DMA2D\_AMTCR register.

The dead time value is stored in the DT[7:0] field of the DMA2D\_AMTCR register. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AXI bus.

The update of the dead time value while the DMA2D is running will be taken into account for the next AXI transfer.

## 18.5 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**Table 128. DMA2D interrupt requests**

Interrupt event	Event flag	Enable control bit
Configuration error	CEIF	CEIE
CLUT transfer complete	CTCIF	CTCIE

Table 128. DMA2D interrupt requests (continued)

Interrupt event	Event flag	Enable control bit
CLUT access error	CAEIF	CAEIE
Transfer watermark	TWF	TWIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

## 18.6 DMA2D registers

### 18.6.1 DMA2D control register (DMA2D\_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CEIE	CTCIE	CAEIE	TWIE	TCIE	TEIE	Res.	Res.	Res.	Res.	Res.	ABORT	SUSP	START
		rw	rw	rw	rw	rw	rw						rs	rw	rs

Bits 31:18 Reserved, must be kept at reset value

Bits 17:16 **MODE**: DMA2D mode

This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.

00: Memory-to-memory (FG fetch only)

01: Memory-to-memory with PFC (FG fetch only with FG PFC active)

10: Memory-to-memory with blending (FG and BG fetch with PFC and blending)

11: Register-to-memory (no FG nor BG, only output stage active)

Bits 15:14 Reserved, must be kept at reset value

Bit 13 **CEIE**: Configuration Error Interrupt Enable

This bit is set and cleared by software.

0: CE interrupt disable

1: CE interrupt enable

Bit 12 **CTCIE**: CLUT transfer complete interrupt enable

This bit is set and cleared by software.

0: CTC interrupt disable

1: CTC interrupt enable

Bit 11 **CAEIE**: CLUT access error interrupt enable

This bit is set and cleared by software.

0: CAE interrupt disable

1: CAE interrupt enable

Bit 10 **TWIE**: Transfer watermark interrupt enable

This bit is set and cleared by software.

0: TW interrupt disable

1: TW interrupt enable

Bit 9 **TCIE**: Transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disable

1: TC interrupt enable

Bit 8 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disable

1: TE interrupt enable

Bits 7:3 Reserved, must be kept at reset value

Bit 2 **ABORT**: Abort

This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.

0: No transfer abort requested

1: Transfer abort requested

Bit 1 **SUSP**: Suspend

This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.

0: Transfer not suspended

1: Transfer suspended

Bit 0 **START**: Start

This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:

- At the end of the transfer
- When the data transfer is aborted by the user application by setting the ABORT bit in DMA2D\_CR
- When a data transfer error occurs
- When the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

### 18.6.2 DMA2D Interrupt Status Register (DMA2D\_ISR)

Address offset: 0x0004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CEIF	CTCIF	CAEIF	TWIF	TCIF	TEIF
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value

Bit 5 **CEIF**: Configuration error interrupt flag

This bit is set when the START bit of DMA2D\_CR, DMA2DFGPFCCR or DMA2D\_BGPFCCR is set and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag

This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag

This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag

This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag

This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag

This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

### 18.6.3 DMA2D interrupt flag clear register (DMA2D\_IFCR)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCEIF	CCTCIF	CAECIF	CTWIF	CTCIF	CTEIF
										rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, must be kept at reset value

- Bit 5 **CCEIF**: Clear configuration error interrupt flag  
Programming this bit to 1 clears the CEIF flag in the DMA2D\_ISR register
- Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag  
Programming this bit to 1 clears the CTCIF flag in the DMA2D\_ISR register
- Bit 3 **CAECIF**: Clear CLUT access error interrupt flag  
Programming this bit to 1 clears the CAEIF flag in the DMA2D\_ISR register
- Bit 2 **CTWIF**: Clear transfer watermark interrupt flag  
Programming this bit to 1 clears the TWIF flag in the DMA2D\_ISR register
- Bit 1 **CTCIF**: Clear transfer complete interrupt flag  
Programming this bit to 1 clears the TCIF flag in the DMA2D\_ISR register
- Bit 0 **CTEIF**: Clear Transfer error interrupt flag  
Programming this bit to 1 clears the TEIF flag in the DMA2D\_ISR register

### 18.6.4 DMA2D foreground memory address register (DMA2D\_FGMAR)

Address offset: 0x000C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the foreground image. This register can only be written when data transfers are disabled. Once the data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

### 18.6.5 DMA2D foreground offset register (DMA2D\_FGOR)

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	LO[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13:0]**: Line offset

Line offset used for the foreground expressed in pixel. This value is used to generate the address. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once a data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

### 18.6.6 DMA2D background memory address register (DMA2D\_BGMR)

Address offset: 0x0014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

### 18.6.7 DMA2D background offset register (DMA2D\_BGOR)

Address offset: 0x0018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	LO[13:0]													
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13:0]**: Line offset

Line offset used for the background image (expressed in pixel). This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

### 18.6.8 DMA2D foreground PFC control register (DMA2D\_FGPFCCR)

Address offset: 0x001C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	CSS[1:0]		AM[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied by the original alpha value according to the alpha mode selected through the AM[1:0] bits.

These bits can only be written when data transfers are disabled. Once a transfer has started, they become read-only.

Bits 23:22 Reserved, must be kept at reset value

Bit 21 **RBS**: Red Blue Swap

This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha

1: Inverted alpha

Bits 19:18 **CSS[1:0]**: Chroma Sub-Sampling

These bits define the chroma sub-sampling mode for YCbCr color mode. Once the transfer has started, these bits are read-only.

00: 4:4:4 (no chroma sub-sampling)

01: 4:2:2

10: 4:2:0

others: meaningless

Bits 17:16 **AM[1:0]**: Alpha mode

These bits select the alpha channel value to be used for the foreground image. They can only be written data the transfer are disabled. Once the transfer has started, they become read-only.

00: No modification of the foreground image alpha channel value

01: Replace original foreground image alpha channel value by ALPHA[7: 0]

10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

other configurations are meaningless

Bits 15:8 **CS[7:0]**: CLUT size

These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value

Bit 5 **START**: Start

This bit can be set to start the automatic loading of the CLUT. It is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in DMA2D\_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer).

Bit 4 **CCM**: CLUT color mode

This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

Bits 3:0 **CM[3:0]**: Color mode

These bits defines the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

0100: ARGB4444

0101: L8

0110: AL44

0111: AL88

1000: L4

1001: A8

1010: A4

1011: YCbCr

others: meaningless

**18.6.9 DMA2D foreground color register (DMA2D\_FGCOLR)**

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]							
								r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GREEN[7:0]								BLUE[7:0]							
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **RED[7:0]**: Red Value

These bits defines the red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7:0]**: Green Value

These bits defines the green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

Bits 7:0 **BLUE[7:0]**: Blue Value

These bits defines the blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

**18.6.10 DMA2D background PFC control register (DMA2D\_BGPFCCR)**

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	Res.	Res.	AM[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw			rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with bits AM[1: 0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:22 Reserved, must be kept at reset value

Bit 21 **RBS**: Red Blue Swap

This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha

1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value

Bits 17:16 **AM[1:0]**: Alpha mode

These bits define which alpha channel value to be used for the background image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

00: No modification of the foreground image alpha channel value

01: Replace original background image alpha channel value by ALPHA[7: 0]

10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

others: meaningless

Bits 15:8 **CS[7:0]**: CLUT size

These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value

**Bit 5 START:** Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in the DMA2D\_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic BackGround CLUT transfer).

**Bit 4 CCM:** CLUT Color mode

These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

**Bits 3:0 CM[3:0]:** Color mode

These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

0100: ARGB4444

0101: L8

0110: AL44

0111: AL88

1000: L4

1001: A8

1010: A4

others: meaningless

### 18.6.11 DMA2D background color register (DMA2D\_BGCOLR)

Address offset: 0x0028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]							
								r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GREEN[7:0]								BLUE[7:0]							
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **RED[7:0]**: Red Value

These bits define the red value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7:0]**: Green Value

These bits define the green value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 **BLUE[7:0]**: Blue Value

These bits define the blue value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 18.6.12 DMA2D foreground CLUT memory address register (DMA2D\_FGCMAR)

Address offset: 0x002C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31: 0 **MA[31:0]**: Memory Address

Address of the data used for the CLUT address dedicated to the foreground image. This register can only be written when no transfer is ongoing. Once the CLUT transfer has started, this register is read-only.

If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.

**18.6.13 DMA2D background CLUT memory address register (DMA2D\_BGCMAR)**

Address offset: 0x0030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 0 **MA[31:0]**: Memory address

Address of the data used for the CLUT address dedicated to the background image. This register can only be written when no transfer is on going. Once the CLUT transfer has started, this register is read-only. If the background CLUT format is 32-bit, the address must be 32-bit aligned.

**18.6.14 DMA2D output PFC control register (DMA2D\_OPFCCR)**

Address offset: 0x0034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RBS	AI	Res.	Res.	Res.	Res.
										rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CM[2:0]		
													rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value

Bit 21 **RBS**: Red Blue Swap

This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

- 0: Regular mode (RGB or ARGB)
- 1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

- 0: Regular alpha
- 1: Inverted alpha

Bits 19:3 Reserved, must be kept at reset value

Bits 2: 0 **CM[2:0]**: Color mode

These bits define the color format of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

- 000: ARGB8888
- 001: RGB888
- 010: RGB565
- 011: ARGB1555
- 100: ARGB4444
- others: meaningless

### 18.6.15 DMA2D output color register (DMA2D\_OCOLR)

Address offset: 0x0038

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RED[4:0]				GREEN[5:0]				BLUE[4:0]								
A	RED[4:0]				GREEN[4:0]				BLUE[4:0]							
ALPHA[3:0]				RED[3:0]				GREEN[3:0]				BLUE[3:0]				
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha Channel Value

These bits define the alpha channel of the output color. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:16 **RED[7:0]**: Red Value

These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7:0]**: Green Value

These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 **BLUE[7:0]**: Blue Value

These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

**18.6.16 DMA2D output memory address register (DMA2D\_OMAR)**

Address offset: 0x003C

Reset value: 0x0000 0000

Bits 31: 0 **MA[31:0]**: Memory Address

Address of the data used for the output FIFO. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

**18.6.17 DMA2D output offset register (DMA2D\_OOR)**

Address offset: 0x0040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	LO[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13:0]**: Line Offset

Line offset used for the output (expressed in pixels). This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

**18.6.18 DMA2D number of line register (DMA2D\_NLR)**

Address offset: 0x0044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PL[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

NL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value

Bits 29:16 **PL[13:0]**: Pixel per lines

Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only. If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15:0]**: Number of lines

Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

**18.6.19 DMA2D line watermark register (DMA2D\_LWR)**

Address offset: 0x0048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **LW[15:0]**: Line watermark

These bits allow to configure the line watermark for interrupt generation.

An interrupt is raised when the last pixel of the watermarked line has been transferred.

These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

**18.6.20 DMA2D AXI master timer configuration register (DMA2D\_AMTCR)**

Address offset: 0x004C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w								r/w

Bits 31:16 Reserved

Bits 15:8 **DT[7:0]**: Dead Time

Dead time value in the AXI clock cycle inserted between two consecutive accesses on the AXI master port. These bits represent the minimum guaranteed number of cycles between two consecutive AXI accesses.

Bits 7:1 Reserved

Bit 0 **EN**: Enable

Enables the dead time functionality.

18.6.21 DMA2D register map

The following table summarizes the DMA2D registers. Refer to [Section 2.2.2 on page 105](#) for the DMA2D register base address.

Table 129. DMA2D register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 19 Nested Vectored Interrupt Controllers

### 19.1 NVIC features

The NVIC includes the following features:

- up to 150 maskable interrupt channels for STM32H7xxx (not including the 16 interrupt lines of Cortex<sup>®</sup>-M7 with FPU)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

For more information on exceptions and NVIC programming, refer to PM0253 programming manual for Cortex<sup>®</sup>-M7.

#### 19.1.1 SysTick calibration value register

The SysTick calibration value is fixed to 18750, which gives a reference time base of 1 ms with the SysTick clock set to 18.75 MHz (HCLK/8, with HCLK set to 150 MHz).

#### 19.1.2 Interrupt and exception vectors

The exception vectors connected to the NVIC are the following: reset, NMI, HardFault, MemManage, Bus Fault, UsageFault, SVCall, DebugMonitor, PendSV, SysTick.

Table 130. NVIC<sup>(1)</sup>

Signal	Priority	NVIC position	Acronym	Description	Address offset
-	-	-	-	Reserved	0x0000 0000
-	-3	-	Reset	Reset	0x0000 0004
-	-2	-	NMI	Non maskable interrupt. The RCC Clock Security System (CSS) is linked to the NMI vector.	0x0000 0008
-	-1	-	HardFault	All classes of fault	0x0000 000C
-	0	-	MemManage	Memory management	0x0000 0010
-	1	-	BusFault	Prefetch fault, memory access fault	0x0000 0014
-	2	-	UsageFault	Undefined instruction or illegal state	0x0000 0018
-	-	-	-	Reserved	0x0000 001C-0x0000 002B

Table 130. NVIC<sup>(1)</sup> (continued)

Signal	Priority	NVIC position	Acronym	Description	Address offset
-	3	-	SVCALL	System service call via SWI instruction	0x0000 002C

1. When different signals are connected to the same NVIC interrupt line, they are OR-ed.

## 20 Extended interrupt and event controller (EXTI)

The Extended Interrupt and event controller (EXTI) manages wakeup through configurable and direct event inputs. It provides wakeup requests to the Power Control, and generates interrupt requests to the CPU NVIC and to the D3 domain DMAMUX2, and events to the CPU event input.

The EXTI wakeup requests allow the system to be woken up from Stop mode, and the CPU to be woken up from CStop mode.

Both the interrupt request and event request generation can also be used in Run modes.

### 20.1 EXTI main features

The EXTI main features are the following:

- All Event inputs allow the CPU to wakeup and to generate a CPU interrupt and/or CPU event
- Some Event inputs allow the user to wakeup the D3 domain for autonomous Run mode and generate an interrupt to the D3 domain, i.e. the DMAMUX2

The asynchronous event inputs are classified in 2 groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse), they have the following features:
  - Selectable active trigger edge
  - Interrupt pending status register bit
  - Individual Interrupt and Event generation mask
  - SW trigger possibility
  - Configurable System D3 domain wakeup events have a D3 Pending mask and status register and may have a D3 interrupt signal.
- Direct events (interrupt and wakeup sources from other peripherals, requiring to be cleared in the peripheral), they feature
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status is provided by the peripheral generating the event)
  - Individual Interrupt and Event generation mask
  - No SW trigger possibility
  - Direct system D3 domain wakeup events have a D3 Pending mask and status register and may have a D3 interrupt signal

### 20.2 EXTI block diagram

As shown in [Figure 79](#), the EXTI consists of a Register block accessed via an APB interface, an Event input Trigger block, and a Masking block.

The Register block contains all EXTI registers.

The Event input trigger block provides Event input edge triggering logic.

The Masking block provides the Event input distribution to the different wakeup, interrupt and event outputs, and their masking.

Figure 79. EXTI block diagram

MSv41947V1

### 20.2.1 EXTI connections between peripherals, CPU, and D3 domain

The peripherals able to generate wakeup events when the system is in Stop mode or the CPU is in CStop mode are connected to an EXTI Configurable event input or Direct Event input:

- Peripheral signals that generate a pulse are connected to an EXTI Configurable Event input. For these events the EXTI provides a CPU status pending bit that has to be cleared.
- Peripheral Interrupt and Wakeup sources that have to be cleared in the peripheral are connected to an EXTI Direct Event input. There is no CPU status pending bit within the EXTI. The Interrupt or Wakeup is cleared by the CPU in the peripheral.

The Event inputs able to wakeup D3 for autonomous Run mode are provided with a D3 domain pending request function, that has to be cleared. This clearing request is taken care of by the signal selected by the Pending clear selection.

The CPU interrupts are connected to their respective CPU NVIC, and, similarly, the CPU event is connected to the CPU rxev input.

The EXTI Wakeup signals are connected to the PWR block, and are used to wakeup the D3 domain and/or the CPU.

The D3 domain interrupts allow the system to trigger events for D3 domain autonomous Run mode operation.

## 20.3 EXTI functional description

Depending on the EXTI Event input type and wakeup target(s), different logic implementations are used. The applicable features are controlled from register bits:

- Active trigger edge enable, by *EXTI rising trigger selection register (EXTI\_RTISR1)*, *EXTI rising trigger selection register (EXTI\_RTISR2)*, *EXTI rising trigger selection register (EXTI\_RTISR3)*, and *EXTI falling trigger selection register (EXTI\_FTISR1)*, *EXTI falling trigger selection register (EXTI\_FTISR2)*, *EXTI falling trigger selection register (EXTI\_FTISR3)*
- Software trigger, by *EXTI software interrupt event register (EXTI\_SWIER1)*, *EXTI software interrupt event register (EXTI\_SWIER2)*, *EXTI software interrupt event register (EXTI\_SWIER3)*
- CPU Interrupt enable, by *EXTI interrupt mask register (EXTI\_CPUIMR1)*, *EXTI interrupt mask register (EXTI\_CPUIMR2)*, *EXTI interrupt mask register (EXTI\_CPUIMR3)*
- CPU Event enable, by *EXTI event mask register (EXTI\_CPEMR1)*, *EXTI event mask register (EXTI\_CPEMR2)*, *EXTI event mask register (EXTI\_CPEMR3)*
- D3 domain wakeup pending, by *EXTI D3 pending mask register (EXTI\_D3PMR1)*, *EXTI D3 pending mask register (EXTI\_D3PMR2)*, *EXTI D3 pending mask register (EXTI\_D3PMR3)*

**Table 131. EXTI Event input configurations and register control<sup>(1)</sup>**

Event input type	Wakeup target(s)	Logic implementation	EXTI_RTISR	EXTI_FTISR	EXTI_SWIER	EXTI_CPUIMR	EXTI_CPEMR	EXTI_D3PMR
Configurable	CPU	Configurable event input, CPU wakeup logic	X	X	X	X	X	-
	Any <sup>(2)</sup>	Configurable event input, Any wakeup logic	X	X	X	X	X	X
Direct	CPU	Direct event input, CPU wakeup logic	-	-	-	X	X	-
	Any <sup>(2)</sup>	Direct event input, Any wakeup logic	-	-	-	X	X	X

1. X indicates that functionality is available.

2. Waking-up D3 domain for autonomous Run mode, and/or CPU.

### 20.3.1 EXTI Configurable event input CPU wakeup

Figure 81 is a detailed representation of the logic associated with Configurable Event inputs which will always wake up the CPU.

Figure 80. Configurable event triggering logic CPU wakeup

The Software interrupt event register allows the system to trigger Configurable events by software, writing the *EXTI software interrupt event register (EXTI\_SWIER1)*, the *EXTI software interrupt event register (EXTI\_SWIER2)*, or the *EXTI software interrupt event register (EXTI\_SWIER3)* register bit.

The rising edge *EXTI rising trigger selection register (EXTI\_RTISR1)*, *EXTI rising trigger selection register (EXTI\_RTISR2)*, *EXTI rising trigger selection register (EXTI\_RTISR3)*, and falling edge *EXTI falling trigger selection register (EXTI\_FTISR1)*, *EXTI falling trigger selection register (EXTI\_FTISR2)*, *EXTI falling trigger selection register (EXTI\_FTISR3)* selection registers allow the system to enable and select the Configurable event active trigger edge or both edges.

The devices feature dedicated interrupt mask registers, namely *EXTI interrupt mask register (EXTI\_CPUIMR1)* and *EXTI interrupt mask register (EXTI\_CPUIMR2)*, *EXTI interrupt mask register (EXTI\_CPUIMR3)*, and *EXTI pending register (EXTI\_CPUPR1)*, *EXTI pending register (EXTI\_CPUPR2)*, *EXTI pending register (EXTI\_CPUPR3)* for Configurable events pending request registers. The CPU pending register will only be set for an unmasked CPU interrupt. Each event provides a individual CPU interrupt to the CPU NVIC. The Configurable events interrupts need to be acknowledged by software in the EXTI\_CPUPR register.

The devices feature dedicated event mask registers, i.e. *EXTI event mask register (EXTI\_CPUEMR1)*, *EXTI event mask register (EXTI\_CPUEMR2)*, and *EXTI event mask register (EXTI\_CPUEMR3)*. The enabled event then generates an event on the CPU. All events for a CPU are OR-ed together into a single CPU event signal. The CPU Pending register (EXTI\_CPUPR) will not be set for an unmasked CPU event.

When a CPU interrupt or CPU event is enabled, the Asynchronous edge detection circuit is reset by the clocked Delay and Rising edge detect pulse generator. This guarantees that the CPU clock is woken up before the Asynchronous edge detection circuit is reset.

*Note: A detected Configurable event, enabled by the CPU, is only cleared when the CPU wakes up.*

### 20.3.2 EXTI configurable event input Any wakeup

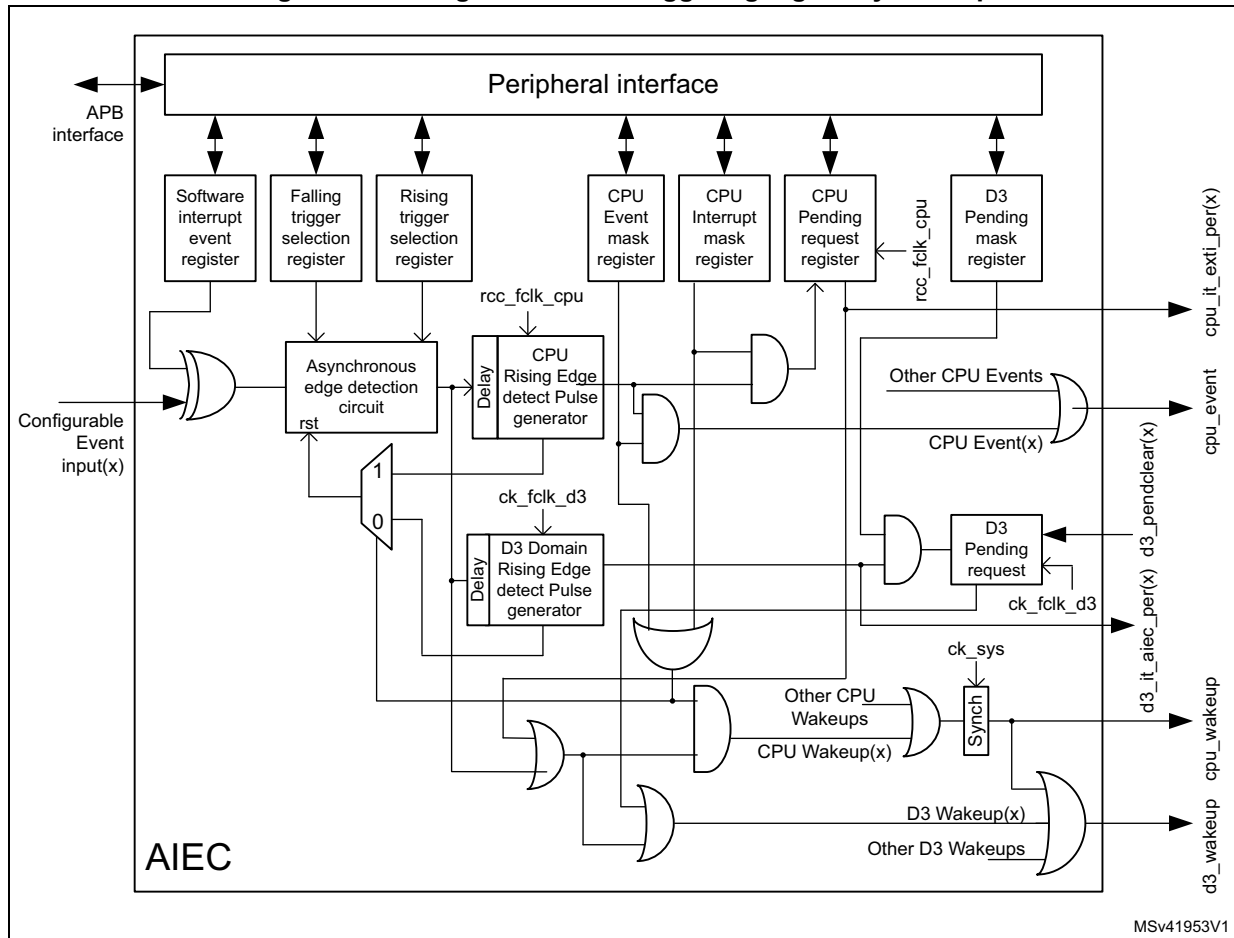

*Figure 81* is a detailed representation of the logic associated with Configurable Event inputs that can wakeup D3 domain for autonomous Run mode and/or CPU (“Any” target). It provides the same functionality as the Configurable event input CPU wakeup, with additional functionality to wake up the D3 domain independently.

When all CPU interrupts and CPU events are disabled, the Asynchronous edge detection circuit is reset by the D3 domain clocked Delay and Rising edge detect pulse generator. This guarantees that the D3 domain clock is woken up before the Asynchronous edge detection circuit is reset.

**Table 132. Configurable Event input Asynchronous Edge detector reset**

EXTI_C1IMR	EXTI_C1EMR	Asynchronous Edge detector reset by
Both = 0		D3 domain clock rising edge detect pulse generator
At least one = 1		CPU clock rising edge detect pulse generator

Figure 81. Configurable event triggering logic Any wakeup

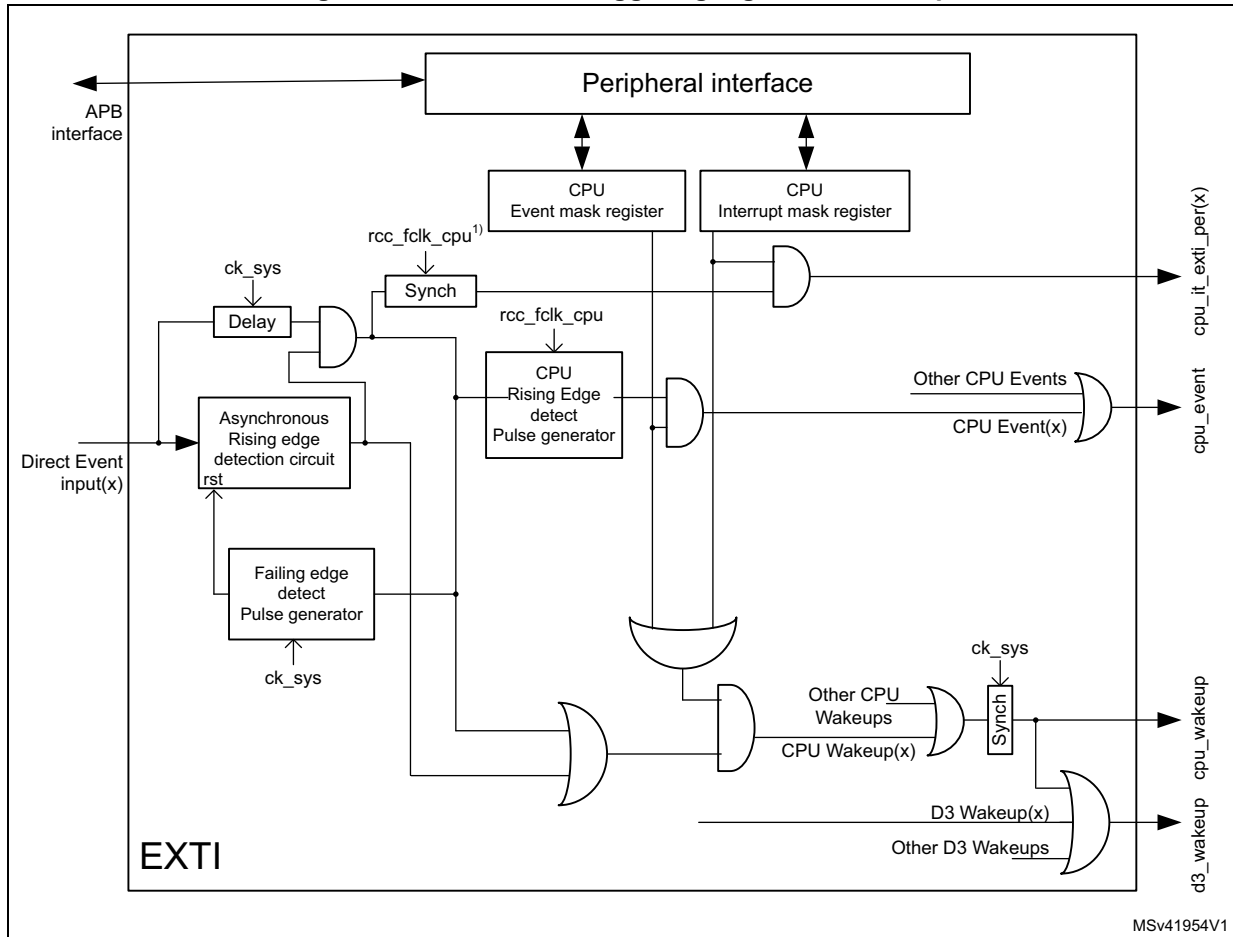

The event triggering logic for “Any” target has additional D3 Pending mask register [EXTI D3 pending mask register \(EXTI\\_D3PMR1\)](#), [EXTI D3 pending mask register \(EXTI\\_D3PMR2\)](#), [EXTI D3 pending mask register \(EXTI\\_D3PMR3\)](#) and D3 Pending request logic. The D3 Pending request logic will only be set for unmasked D3 Pending events. The D3 Pending request logic keeps the D3 domain in Run mode until the D3 Pending request logic is cleared by the selected D3 domain pendclear source.

### 20.3.3 EXTI direct event input CPU wakeup

Figure 82 is a detailed representation of the logic associated with Direct Event inputs waking up the CPU.

Direct events only provide CPU interrupt enable and CPU event enable functionality.

Figure 82. Direct event triggering logic CPU Wakeup

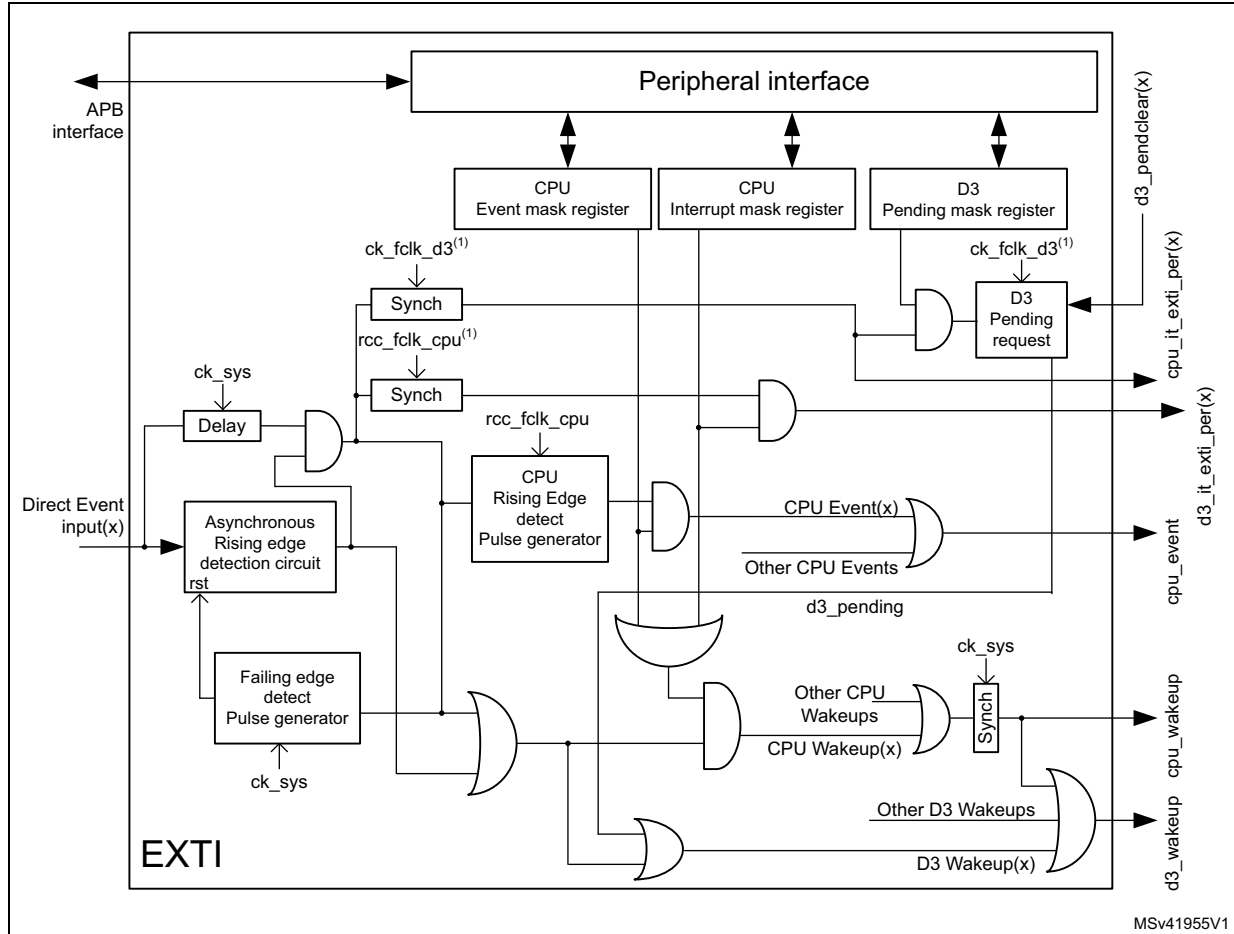

1. The CPU interrupt for asynchronous Direct Event inputs (peripheral Wakeup signals) is synchronized with the CPU clock. The synchronous Direct Event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt without resynchronization.

### 20.3.4 EXTI direct event input Any wakeup

Figure 83 is a detailed representation of the logic associated with Direct Event inputs waking up D3 domain for autonomous Run mode and/or CPU, (“Any” target). It provides the same functionality as the Direct event input CPU wakeup, plus additional functionality to wakeup the D3 domain independently.

Figure 83. Direct event triggering logic Any Wakeup

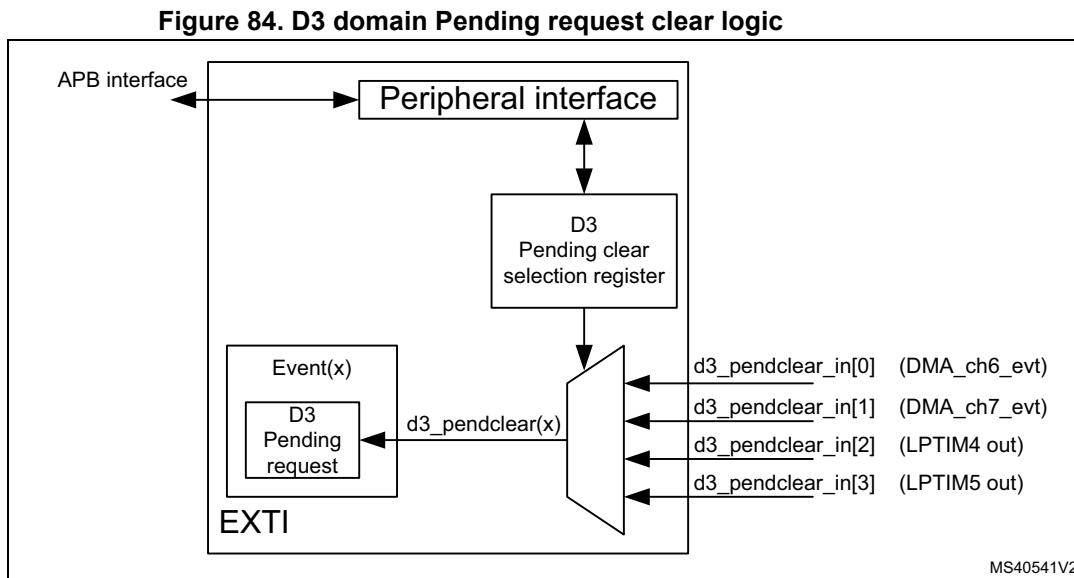

1. The CPU interrupt and D3 domain interrupt for asynchronous Direct Event inputs (peripheral Wakeup signals) are synchronized, respectively, with the CPU clock and the D3 domain clock. The synchronous Direct Event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt and the D3 domain interrupt without resynchronization in the EXTI.

### 20.3.5 EXTI D3 pending request clear selection

Event inputs able to wake up D3 domain for autonomous Run mode have D3 Pending request logic that can be cleared by the selected D3 pendclear source. For each D3 Pending request a D3 domain pendclear source can be selected from four different inputs.

Figure 84 is a detailed representation of the logic selecting the D3 pendclear source.

The D3 Pending request clear selection registers *EXTI D3 pending clear selection register low (EXTI\_D3PCR1L)*, *EXTI D3 pending clear selection register high (EXTI\_D3PCR1H)*, *EXTI D3 pending clear selection register low (EXTI\_D3PCR2L)*, *EXTI D3 pending clear selection register high (EXTI\_D3PCR2H)*, *EXTI D3 pending clear selection register low (EXTI\_D3PCR3L)* and *EXTI D3 pending clear selection register high (EXTI\_D3PCR3H)* allow the system to select the source to reset the D3 Pending request.

## 20.4 EXTI event input mapping

For the sixteen GPIO Event inputs the associated IOPORT pin has to be selected in the SYSCFG register SYSCFG\_EXTICRn. The same pin from each IOPORT maps to the corresponding EXTI Event input.

The wakeup capabilities of each Event input are detailed in [Table 133](#). An Event input can either wake up the CPU, and in the case of “Any” can also wake up D3 domain for autonomous Run mode.

The EXTI Event inputs with a connection to the CPU NVIC are indicated in the *Connection to NVIC* column. For the EXTI events not having a connection to the NVIC, the peripheral interrupt is directly connected to the NVIC in parallel with the connection to the EXTI.

All EXTI Event inputs are OR-ed together and connected to the CPU event input (rxev).

Table 133. EXTI Event input mapping

**Table 133. EXTI Event input mapping (continued)**

Event input	Source	Event input type	Wakeup target(s)	Connection to NVIC
84	Reserved	-	-	-
85	HDMI-CEC wakeup	Configurable	CPU only	Yes
86	ETHERNET wakeup	Configurable	CPU only	Yes
87	HSECSS interrupt	Direct	CPU only	No <sup>(4)</sup>
88	Reserved	-	-	-

1. PVD and AVD signals are OR-ed together on the same EXTI event input.
2. RTC Tamper, RTC timestamp and RCC LSECSS signals are OR-ed together on the same EXTI event input.
3. Not available on CPU NVIC, to be used for system wakeup only or CPU event input (rxev).
4. Available on CPU NVIC directly from the peripheral

## 20.5 EXTI functional behavior

The Direct event inputs are enabled in the respective peripheral generating the event. The Configurable events are enabled by enabling at least one of the trigger edges.

When in Stop mode an event will always wake up the D3 domain. In system Run and Stop modes an event will always generate an associated D3 domain interrupt. An event will only wake up the CPU when the event associated CPU interrupt is unmasked and/or the CPU event is unmasked.

**Table 134. Masking functionality**

CPU		Configurable event inputs PRx bits of EXTI_CPUPR	CPU			D3 domain wakeup
Interrupt enable MRx bits of EXTI_CPUIMR	Event enable MRx bits of EXTI_CPEMR		Interrupt	Event	Wakeup	
0	0	No	Masked	Masked	Masked	Yes <sup>(1)</sup> / Masked <sup>(2)</sup>
0	1	No	Masked	Yes	Yes	Yes
1	0	Status latched	Yes	Masked	Yes	Yes
1	1	Status latched	Yes	Yes	Yes	Yes

1. Only for Event inputs that allow the system to wakeup D3 domain for autonomous Run mode (Any target).
2. For Event inputs that will always wake up CPU.

For Configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI\_CPUPR is set and the CPU interrupt signal is activated. EXTI\_CPUPR PRx pending bit shall be cleared by software writing it to '1'. This will clear the CPU interrupt.

For Direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked the corresponding CPU interrupt signal is activated.

The CPU event has to be unmasked to generate an event. When the enabled edge(s) occur on the Event input a CPU event pulse is generated. There is no CPU Event pending bit.

Both a CPU interrupt and a CPU event may be enabled on the same Event input. They will both trigger the same Event input condition(s).

For the Configurable Event inputs an event input request can be generated by software when writing a '1' in the software interrupt/event register EXTI\_SWIER.

Whenever an Event input is enabled and a CPU interrupt and/or CPU event is unmasked, the Event input will also generate a D3 domain wakeup next to the CPU wakeup.

Some Event inputs are able to wakeup the D3 domain autonomous Run mode, in this case the CPU interrupt and CPU event are masked, preventing the CPU to be woken up. Two D3 domain autonomous Run mode wakeup mechanisms are supported:

- D3 domain wakeup without pending (EXTI\_D3PMR = 0)
  - On a Configurable Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal automatically after the Delay + Rising Edge detect Pulse generator.
  - On a Direct Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal after the Direct Event input signal is cleared.
- D3 domain wakeup with pending (EXTI\_D3PMR = 1)
  - On a Configurable Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal after the Delay + Rising Edge detect Pulse generator and when the D3 Pending request is cleared.
  - On a Direct Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal after the Direct Event input signal is cleared and when the D3 Pending request is cleared.

### 20.5.1 EXTI CPU interrupt procedure

- Unmask the Event input interrupt by setting the corresponding mask bits in the EXTI\_CPUIMR register.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI\_RTSR and EXTI\_FTSR registers.
- Enable the associated interrupt source in the CPU NVIC or use the SEVONPEND, so that an interrupt coming from the CPU interrupt signal is detectable by the CPU after a WFI/WFE instruction.
  - For Configurable event inputs the associated EXTI pending bit needs to be cleared.

### 20.5.2 EXTI CPU event procedure

- Unmask the Event input by setting the corresponding mask bits of the EXTI\_CPUEMR register.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI\_RTSR and EXTI\_FTSR registers.
- The CPU event signal is detected by the CPU after a WFE instruction.
  - For Configurable event inputs there is no EXTI pending bit to clear.

### 20.5.3 EXTI CPU wakeup procedure

- Unmask the Event input by setting at least one of the corresponding mask bits in the EXTI\_CPUIMR and/or EXTI\_CPUEMR registers. The CPU wakeup is generated at the same time as the unmasked CPU interrupt and/or CPU event.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI\_RTISR and EXTI\_FTISR registers.
- Direct Events will automatically generate a CPU wakeup.

### 20.5.4 EXTI D3 domain wakeup for autonomous Run mode procedure

- Mask the Event input for waking up the CPU, by clearing both the corresponding mask bits in the EXTI\_CPUIMR and/or EXTI\_CPUEMR registers.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI\_RTISR and EXTI\_FTISR registers.
- Direct Events will automatically generate a D3 domain wakeup.
- Select the D3 domain wakeup mechanism in EXTI\_D3PMR.
  - When D3 domain wakeup without pending (EXTI\_PMR = 0) is selected, the Wakeup will be cleared automatically following the clearing of the Event input.
  - When D3 domain wakeup with pending (EXTI\_PMR = 1) is selected the Wakeup needs to be cleared by a selected D3 domain pendclear source.  
A pending D3 domain wakeup signal can also be cleared by FW clearing the associated EXTI\_D3PMR register bit.
- After the D3 domain wakeup a D3 domain interrupt is generated.
  - Configurable Event inputs will generate a pulse on D3 domain interrupt.
  - Direct Event inputs will activate the D3 domain interrupt until the event input is cleared in the peripheral.

### 20.5.5 EXTI software interrupt/event trigger procedure

Any of the Configurable Event inputs can be triggered from the software interrupt/event register (the associated CPU interrupt and/or CPU event shall be enabled by their respective procedure).

- Enable the Event input by setting at least one of the corresponding edge trigger bits in the EXTI\_RTISR and/or EXTI\_FTISR registers.
- Unmask the software interrupt/event trigger by setting at least one of the corresponding mask bits in the EXTI\_CPUIMR and/or EXTI\_CPUEMR registers.
- Trigger the software interrupt/event by writing “1” to the corresponding bit in the EXTI\_SWIER register.
- The Event input may be disabled by clearing the EXTI\_RTISR and EXTI\_FTISR register bits.

*Note:* An edge on the Configurable event input will also trigger an interrupt/event.

A software trigger can be used to set the D3 Pending request logic, keeping the D3 domain in Run until the D3 Pending request logic is cleared.

## 20.6 EXTI register description

Every register can only be accessed with 32-bit (word). A byte or half-word cannot be read or written.

### 20.6.1 EXTI rising trigger selection register (EXTI\_RTSTR1)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TR21	TR20	TR19	TR18	TR17	TR16
										r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TR15	TR14	TR13	TR12	TR11	TR10	TR9	TR8	TR7	TR6	TR5	TR4	TR3	TR2	TR1	TR0
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:22 Reserved, must be kept at reset value (0).

Bits 21:0 **TRx**: Rising trigger event configuration bit of Configurable Event input x.<sup>(1)</sup>

0: Rising trigger disabled (for Event and Interrupt) for input line

1: Rising trigger enabled (for Event and Interrupt) for input line

- The Configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a rising edge on the Configurable event input occurs during writing of the register, the associated pending bit will not be set. Rising and falling edge triggers can be set for the same Configurable Event input. In this case, both edges generate a trigger.

### 20.6.2 EXTI falling trigger selection register (EXTI\_FTSTR1)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TR21	TR20	TR19	TR18	TR17	TR16

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:22 Reserved, must be kept at reset value (0).

Bits 21:0 **TRx**: Falling trigger event configuration bit of Configurable Event input x.<sup>(1)</sup>

0: Falling trigger disabled (for Event and Interrupt) for input line

1: Falling trigger enabled (for Event and Interrupt) for input line.

- The Configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a falling edge on the Configurable event input occurs during writing of the register, the associated pending bit will not be set. Rising and falling edge triggers can be set for the same Configurable Event input. In this case, both edges generate a trigger.

### 20.6.3 EXTI software interrupt event register (EXTI\_SWIER1)

Address offset: 0x08  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWIER 21	SWIER 20	SWIER 19	SWIER 18	SWIER 17	SWIER 16

Bits 3:0 Reserved, must be kept at reset value (0).

### 20.6.12 EXTI D3 pending clear selection register high (EXTI\_D3PCR2H)

Address offset: 0x34  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	PCS53		PCS52		PCS51		PCS50		PCS49		PCS48	
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value (0).

Bits 11:0 **PCSx**: D3 Pending request clear input signal selection on Event input x= truncate ((n+96)/2)

- 00: DMA ch6 event selected as D3 domain pendclear source
- 01: DMA ch7 event selected as D3 domain pendclear source
- 10: LPTIM4 out selected as D3 domain pendclear source
- 11: LPTIM5 out selected as D3 domain pendclear source

### 20.6.13 EXTI rising trigger selection register (EXTI\_RTSR3)

Address offset: 0x40  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TR86	TR85	TR84	Res.	TR82	Res.	Res.
									rw	rw	rw		rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:20 **TRx**: Rising trigger event configuration bit of Configurable Event input x+64.<sup>(1)</sup>  
 0: Rising trigger disabled (for Event and Interrupt) for input line  
 1: Rising trigger enabled (for Event and Interrupt) for input line

Bit 19 Reserved, must be kept at reset value (0).

Bit 18 **TRx**: Rising trigger event configuration bit of Configurable Event input x+64.<sup>(1)</sup>  
 0: Rising trigger disabled (for Event and Interrupt) for input line  
 1: Rising trigger enabled (for Event and Interrupt) for input line

Bits 17:0 Reserved, must be kept at reset value (0).

- The Configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a rising edge on the Configurable event input occurs during writing of the register, the associated pending bit will not be set. Rising and falling edge triggers can be set for the same Configurable Event input. In this case, both edges generate a trigger.

### 20.6.14 EXTI falling trigger selection register (EXTI\_FTSTR3)

Address offset: 0x44  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TR86	TR85	TR84	Res.	TR82	Res.	Res.
									rw	rw	rw		rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:20 **TRx**: Falling trigger event configuration bit of Configurable Event input x+64.<sup>(1)</sup>  
 0: Falling trigger disabled (for Event and Interrupt) for input line  
 1: Falling trigger enabled (for Event and Interrupt) for input line

Bit 19 Reserved, must be kept at reset value (0).

Bit 18 **TRx**: Falling trigger event configuration bit of Configurable Event input x+64.<sup>(1)</sup>  
 0: Falling trigger disabled (for Event and Interrupt) for input line  
 1: Falling trigger enabled (for Event and Interrupt) for input line

Bits 17:0 Reserved, must be kept at reset value (0).

- The Configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a falling edge on the Configurable event input occurs during writing of the register, the associated pending bit will not be set. Rising and falling edge triggers can be set for the same Configurable Event input. In this case, both edges generate a trigger.

### 20.6.15 EXTI software interrupt event register (EXTI\_SWIER3)

Address offset: 0x48

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWIER 86	SWIER 85	SWIER 84	Res.	SWIER 82	Res.	Res.
									rw	rw	rw		rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:20 **SWIERx**: Software interrupt on line x+64  
 Will always return 0 when read.  
 0: Writing 0 has no effect.  
 1: Writing a 1 to this bit will trigger an event on line x. This bit is auto cleared by HW.

Bit 19 Reserved, must be kept at reset value (0).

Bit 18 **SWIERx**: Software interrupt on line x+64  
 Will always return 0 when read.  
 0: Writing 0 has no effect.  
 1: Writing a 1 to this bit will trigger an event on line x. This bit is auto cleared by HW.

Bits 17:0 Reserved, must be kept at reset value (0).

### 20.6.16 EXTI D3 pending mask register (EXTI\_D3PMR3)

Address offset: 0x4C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	MR88	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:25 Reserved, must be kept at reset value (0).

Bit 24 **MRx**: D3 Pending Mask on Event input x+64

0: D3 Pending request from Line x+64 is masked. Writing this bit to 0 will also clear the D3 Pending request.

1: D3 Pending request from Line x+64 is unmasked. The D3 domain pending signal when triggered will keep D3 domain wakeup active until cleared.

Bits 23:0 Reserved, must be kept at reset value (0).

### 20.6.17 EXTI D3 pending clear selection register low (EXTI\_D3PCR3L)

Address offset: 0x50

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:0 Reserved, must be kept at reset value (0).

### 20.6.18 EXTI D3 pending clear selection register high (EXTI\_D3PCR3H)

Address offset: 0x54

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCS88	
														rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:18 Reserved, must be kept at reset value (0).

Bits 17:16 **PCSx**: D3 Pending request clear input signal selection on Event input x= truncate ((n+160)/2)

00: DMA ch6 event selected as D3 domain pendclear source

01: DMA ch7 event selected as D3 domain pendclear source

10: LPTIM4 out selected as D3 domain pendclear source

11: LPTIM5 out selected as D3 domain pendclear source

Bits 15:0 Reserved, must be kept at reset value (0).

### 20.6.19 EXTI interrupt mask register (EXTI\_CPUIMR1)

Address offset: 0x80

Reset value: 0xFFC0 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR31	MR30	MR29	MR28	MR27	MR26	MR25	MR24	MR23	MR22	MR21	MR20	MR19	MR18	MR17	MR16
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR15	MR14	MR13	MR12	MR11	MR10	MR9	MR8	MR7	MR6	MR5	MR4	MR3	MR2	MR1	MR0
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:22 **MRx**: CPU interrupt Mask on Direct Event input x<sup>(1)</sup>

- 0: Interrupt request from Line x is masked
- 1: Interrupt request from Line x is unmasked

Bits 21:0 **MRx**: CPU interrupt Mask on Configurable Event input x<sup>(2)</sup>

- 0: Interrupt request from Line x is masked
- 1: Interrupt request from Line x is unmasked

1. The reset value for Direct Event inputs is set to '1' in order to enable the interrupt by default.
2. The reset value for Configurable Event inputs is set to '0' in order to disable the interrupt by default.

### 20.6.20 EXTI event mask register (EXTI\_CPUEMR1)

Address offset: 0x84

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR31	MR30	MR29	MR28	MR27	MR26	MR25	MR24	MR23	MR22	MR21	MR20	MR19	MR18	MR17	MR16
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR15	MR14	MR13	MR12	MR11	MR10	MR9	MR8	MR7	MR6	MR5	MR4	MR3	MR2	MR1	MR0
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:0 **MRx**: CPU Event mask on Event input x

- 0: Event request from Line x is masked
- 1: Event request from Line x is unmasked

### 20.6.21 EXTI pending register (EXTI\_CPUPR1)

Address offset: 0x88

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PR21	PR21	PR19	PR18	PR17	PR16
										rc1	rc1	rc1	rc1	rc1	rc1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PR15	PR14	PR13	PR12	PR11	PR10	PR9	PR8	PR7	PR6	PR5	PR4	PR3	PR2	PR1	PR0
rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1	rc1

Bits 31:22 Reserved, must be kept at reset value (0).

Bits 21:0 **PRx**: Configurable event inputs x Pending bit

0: No trigger request occurred

1: selected trigger request occurred

This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

### 20.6.22 EXTI interrupt mask register (EXTI\_CPUIMR2)

Address offset: 0x90

Reset value: 0xFFFF5 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR63	MR62	MR61	MR60	MR59	MR58	MR57	MR56	MR55	MR54	MR53	MR52	MR51	MR50	MR49	MR48
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR47	MR46	Res.	MR44	MR43	MR42	MR41	MR40	MR39	MR38	MR37	MR36	MR35	MR34	MR33	MR32
rw	rw	1	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 **MRx**: CPU Interrupt Mask on Direct Event input x+32<sup>(1)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bit 19 **MRx**: CPU interrupt Mask on Configurable Event input x+32<sup>(2)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bit 18 **MRx**: CPU Interrupt Mask on Direct Event input x+32<sup>(1)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bit 17 **MRx**: CPU interrupt Mask on Configurable Event input x+32<sup>(2)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bits 16:14 **MRx**: CPU Interrupt Mask on Direct Event input x+32 <sup>(1)</sup>

- 0: Interrupt request from Line x is masked
- 1: Interrupt request from Line x is unmasked

Bit 13 Reserved, must be kept at reset value (1).

Bits 12:0 **MRx**: CPU Interrupt Mask on Direct Event input x+32 <sup>(1)</sup>

- 0: Interrupt request from Line x is masked
- 1: Interrupt request from Line x is unmasked

1. The reset value for Direct Event inputs is set to '1' in order to enable the interrupt by default.
2. The reset value for Configurable Event inputs is set to '0' in order to disable the interrupt by default.

### 20.6.23 EXTI event mask register (EXTI\_CPUEMR2)

Address offset: 0x94

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR63	MR62	MR61	MR60	MR59	MR58	MR57	MR56	MR55	MR54	MR53	MR52	MR51	MR50	MR49	MR48
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR47	MR46	Res.	MR44	MR43	MR42	MR41	MR40	MR39	MR38	MR37	MR36	MR35	MR34	MR33	MR32
rW	rW	0	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 31:14 **MRx**: CPU Event mask on Event input x+32

- 0: Event request from Line x is masked
- 1: Event request from Line x is unmasked

Bit 13 Reserved, must be kept at reset value (0).

Bits 12:0 **MRx**: CPU Event mask on Event input x+32

- 0: Event request from Line x is masked
- 1: Event request from Line x is unmasked

### 20.6.24 EXTI pending register (EXTI\_CPUPR2)

Address offset: 0x98

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PR51	Res.	PR49	Res.
												rc1		rc1	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:20 Reserved, must be kept at reset value (0).

Bit 19 **PRx**: Configurable event inputs x+32 Pending bit

0: No trigger request occurred

1: selected trigger request occurred

This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bit 18 Reserved, must be kept at reset value (0).

Bit 17 **PRx**: Configurable event inputs x+32 Pending bit

0: No trigger request occurred

1: selected trigger request occurred

This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 16:0 Reserved, must be kept at reset value (0).

### 20.6.25 EXTI interrupt mask register (EXTI\_CPUIMR3)

Address offset: 0xA0

Reset value: 0x018B FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res	Res	Res	Res	Res	Res	Res	MR88	MR87	MR86	MR85	MR84	Res	MR82	Res	MR80
							rw	rw	rw	rw	rw		rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR79	MR78	MR77	MR76	MR75	MR74	MR73	MR72	MR71	MR70	MR69	MR68	MR67	MR66	MR65	MR64
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value (0).

Bits 24:23 **MRx**: CPU Interrupt Mask on Direct Event input x+64 <sup>(1)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bits 22:20 **MRx**: CPU interrupt Mask on Configurable Event input x+64 <sup>(2)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bit 19 Reserved, must be kept at reset value (1).

Bit 18 **MRx**: CPU interrupt Mask on Configurable Event input x+64 <sup>(2)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

Bit 17 Reserved, must be kept at reset value (1).

Bits 16:0 **MRx**: CPU Interrupt Mask on Direct Event input x+64 <sup>(1)</sup>

0: Interrupt request from Line x is masked

1: Interrupt request from Line x is unmasked

1. The reset value for Direct Event inputs is set to '1' in order to enable the interrupt by default.
2. The reset value for Configurable Event inputs is set to '0' in order to disable the interrupt by default.

### 20.6.26 EXTI event mask register (EXTI\_CPUEMR3)

Address offset: 0xA4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value (0).

Bits 24:0 **MRx**: CPU Event mask on Event input x+64

- 0: Event request from Line x is masked
- 1: Event request from Line x is unmasked

### 20.6.27 EXTI pending register (EXTI\_CPUPR3)

Address offset: 0xA8

Reset value: undefined

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PR86	PR85	PR84	Res.	PR82	Res.	Res.
									rc1	rc1	rc1		rc1		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value (0).

Bits 22:20 **PRx**: Configurable event inputs x+64 Pending bit

- 0: No trigger request occurred
  - 1: selected trigger request occurred
- This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bit 19 Reserved, must be kept at reset value (0).

Bit 18 **PRx**: Configurable event inputs x+64 Pending bit

- 0: No trigger request occurred
  - 1: selected trigger request occurred
- This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 17:0 Reserved, must be kept at reset value (0).

### 20.6.28 EXTI register map

The following table gives the EXTI register map and the reset values.

**Table 135. Asynchronous interrupt/event controller register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## 21 Cyclic redundancy check calculation unit (CRC)

### 21.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

### 21.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7  
$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data

## 21.3 CRC functional description

### 21.3.1 CRC block diagram

Figure 85. CRC calculation unit block diagram

### 21.3.2 CRC internal signals

Table 136. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

### 21.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC\_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC\_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC\_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit

An input buffer allows to immediately write a second data without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV\_IN[1:0] bits in the CRC\_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:

0x58D43CB2 with bit-reversal done by byte

0xD458B23C with bit-reversal done by half-word

0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV\_OUT bit in the CRC\_CR register.

The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC\_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC\_INIT register. The CRC\_DR register is automatically initialized upon CRC\_INIT register write access.

The CRC\_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC\_CR register.

### Polynomial programmability

The polynomial coefficients are fully programmable through the CRC\_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC\_CR register. Even polynomials are not supported.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC\_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC\_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

## 21.4 CRC registers

### 21.4.1 Data register (CRC\_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

Bits 31:0 **DR[31:0]**: Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

### 21.4.2 Independent data register (CRC\_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC\_CR register

### 21.4.3 Control register (CRC\_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REV_OUT	REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
								rw	rw	rw	rw	rw			rs

Bits 31:8 Reserved, must be kept cleared.

Bit 7 **REV\_OUT**: Reverse output data

This bit controls the reversal of the bit order of the output data.

0: Bit order not affected

1: Bit-reversed output format

Bits 6:5 **REV\_IN[1:0]**: Reverse input data

These bits control the reversal of the bit order of the input data

00: Bit order not affected

01: Bit reversal done by byte

10: Bit reversal done by half-word

11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept cleared.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC\_INIT register. This bit can only be set, it is automatically cleared by hardware

### 21.4.4 Initial CRC value (CRC\_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw															

Bits 31:0 **CRC\_INIT**: Programmable initial CRC value  
 This register is used to write the CRC initial value.

### 21.4.5 CRC polynomial (CRC\_POL)

Address offset: 0x14  
 Reset value: 0x04C11DB7

Bits 31:0 **POL[31:0]**: Programmable polynomial  
 This register is used to write the coefficients of the polynomial to be used for CRC calculation.  
 If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

### 21.4.6 CRC register map

Table 137. CRC register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Reset value	0x04C11DB7																															

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 22 Flexible memory controller (FMC)

The Flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPDDR SDRAM) controller

### 22.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPDDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16- or 32-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

The Write FIFO is common to all memory controllers and consists of:

- a Write Data FIFO which stores the data to be written to the memory
  - a Write Address FIFO which stores the address (up to 28 bits) plus the data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the burst is broken into two FIFO entries.
- Cacheable Read FIFO with 6 x64-bit depth (6 x14-bit address tag) for SDRAM controller.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. However, only few bits can be changed on-the-fly.

- ECCEN and PBEN bits in FMC\_PCR register
- IFS, IRS and ILS bits in FMC\_SR register
- MODE[2:0], CTB1/CTB2, NRFS and MRD bits in FMC\_SDCMR register
- REIE and CRE bits in the FMC\_SDRTR register.

Follow the below sequence to modify some parameters while FMC is enabled:

1. First disable the FMC controller to prevent any further accesses to any memory controller during register modification.
2. Update all required configurations.
3. Enable the FMC controller again.

When the SDRAM controller is used, if the SDCLK Clock ratio or refresh rate has to be modified after initialization phase, the following procedure must be followed.

1. Put the SDRAM device in Self-refresh mode.
2. Disable the FMC controller by resetting the FMCEN bit in the FMC\_BCR1 register.
3. Update the required parameters.
4. Enable the FMC controller once all parameters are updated.
5. Then, send the Clock Configuration Enable command to exit Self-fresh mode.

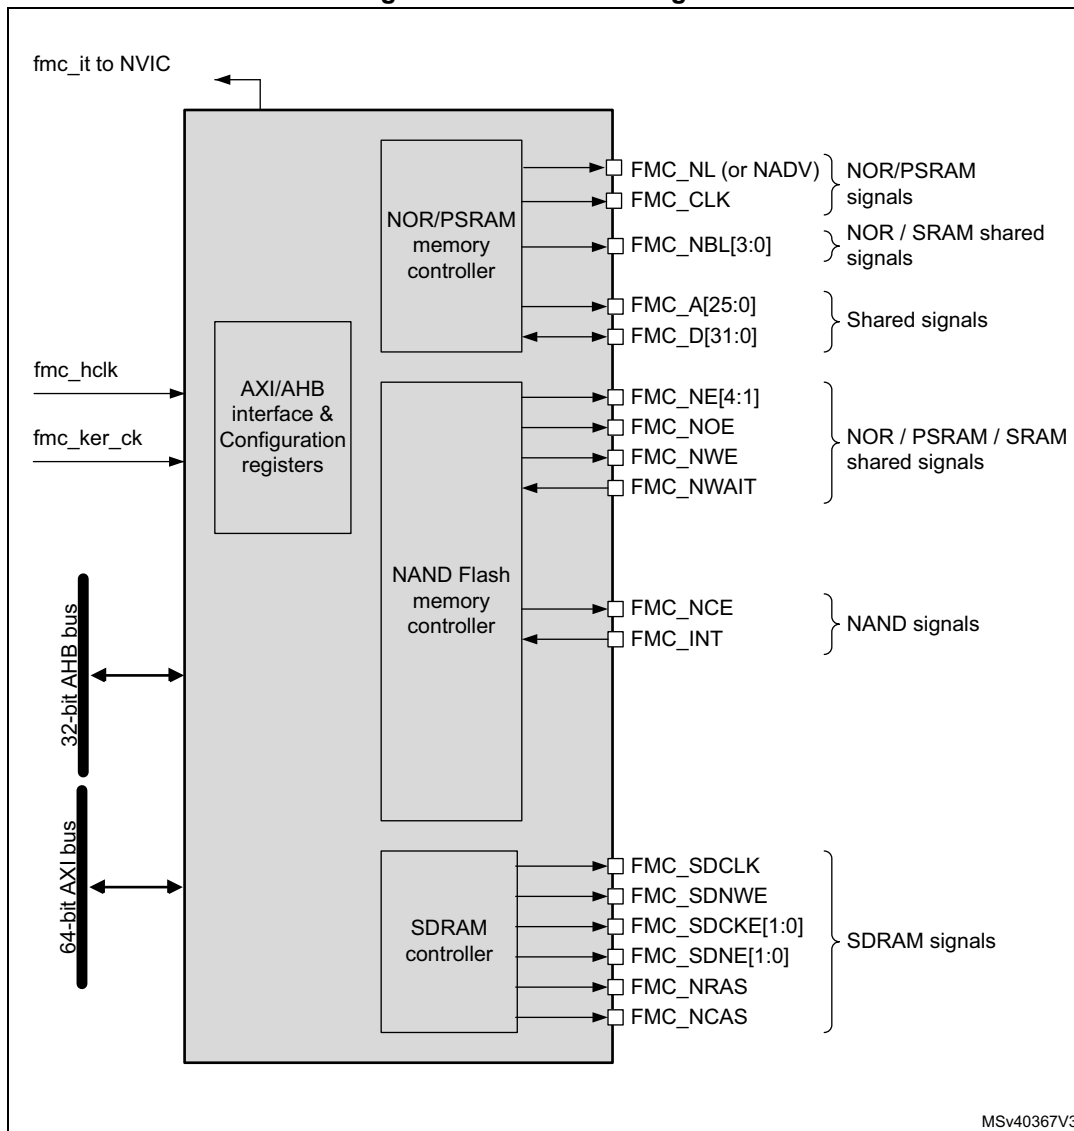

## 22.2 FMC block diagram

The FMC consists of the following main blocks:

- The NOR Flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the figure below.

Figure 86. FMC block diagram

## 22.3 FMC internal signals

[Table 138](#) gives the list of FMC internal signals. FMC pins (or external signals) are described in [Section 22.7.1: External memory interface signals](#).

**Table 138. FMC pins**

Names	Signal type	Description
fmc_it	Digital output	FMC interrupt
fmc_ker_ck	Digital input	FMC kernel clock
fmc_hclk	Digital input	FMC interface clock

## 22.4 AHB interface

The AHB slave interface allows internal CPUs to configure the FMC registers.

The AHB clock (fmc\_hclk) is the reference clock for the FMC register accesses.

## 22.5 AXI interface

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32-, 16- or 8-bit accesses according to data size accesses. The FMC Chip Select (FMC\_NEx) does not toggle between consecutive accesses except in case of accesses in Mode D when the extended mode is enabled.

The FMC generates an AXI slave error when one of the following conditions is met:

- Reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- Reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC\_BCRx register.
- Writing to a write protected SDRAM bank (WP bit set in the SDRAM\_SDCRx register).
- Violation of the SDRAM address range (access to reserved address range)
- Attempting to read/write access from/to SDRAM bank when it is not yet initialized

The FMC generates an AXI decoder error when ADDR[31:28] address bits are not supported by the FMC bank base address following the BMAP[1:0] bits configuration.

The kernel clock for the FMC controller is the asynchronous fmc\_ker\_ck clock (refer to [Section 8: Reset and Clock Control \(RCC\)](#) for fmc\_ker\_ck clock source selection).

### 22.5.1 Supported memories and transactions

#### General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules can be followed, depending on AXI transaction size versus memory data size:

- AXI transaction size and memory data size are equal to prevent issues from occurring.
- AXI transaction size is greater than the memory size:  
In this case, the FMC splits the AXI transaction into smaller consecutive memory accesses to meet the external data width.
- AXI transaction size is smaller than the memory size:  
The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM, SDRAM)  
In this case, the FMC allows read/write transactions and accesses the right data through its NBL[3:0] byte lanes.  
Bytes to be written are addressed by NBL[3:0].  
All memory bytes are read (NBL[3:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)  
This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in byte mode (only 16-bit words can be read/written from/to the Flash memory), write transactions are not allowed while read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

### Wrap support for NOR Flash/PSRAM and SDRAM

The synchronous memories must be configured in linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read is split into two linear burst transactions.
- The write is split into two linear burst transactions if the write FIFO is enabled and into several linear burst transactions if the write FIFO is disabled.

### Configuration registers

The FMC can be configured through a set of registers. Refer to [Section 22.7.6](#), for a detailed description of the NOR Flash/PSRAM controller registers. Refer to [Section 22.8.7](#), for a detailed description of the NAND Flash registers and to [Section 22.9.5](#) for a detailed description of the SDRAM controller registers.

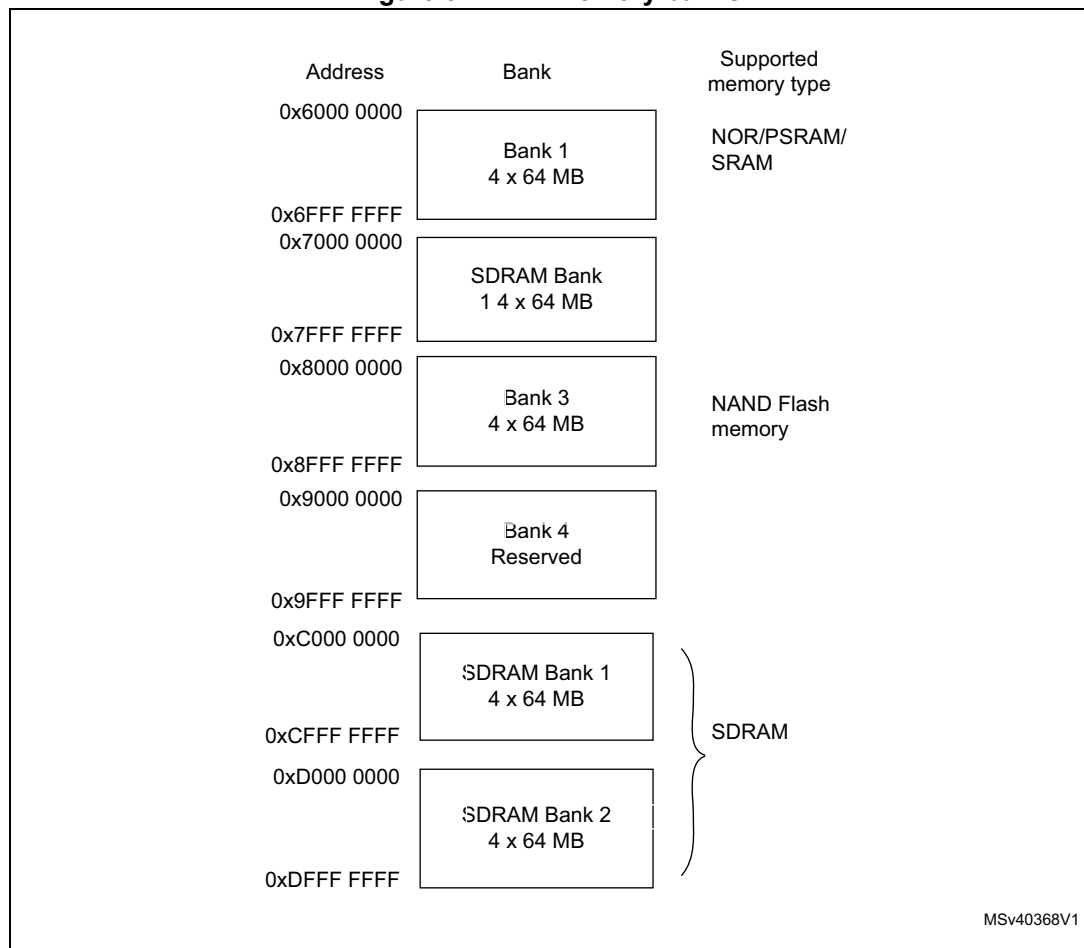

## 22.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see [Figure 87](#)):

- Bank 1 is used to address up to 4 NOR Flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 2 is used for SDRAM device, SDRAM bank 1 or SDRAM bank 2 depending on BMAP bits configuration.
- Bank 3 is used to address NAND Flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 4 and 5 are used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

**Figure 87. FMC memory banks**

The FMC bank mapping can be modified through the BMAP[1:0] bits in the FMC\_BCR1 register. [Table 139](#) shows the configuration to swap the NOR/PSRAM bank with SDRAM banks or remap the SDRAM bank2, thus allowing to access the SDRAM banks at two different address mapping.

**Table 139. FMC bank mapping options**

Start -End address	BMAP[1:0]=00 (Default mapping)	BMAP[1:0]=01 NOR/PSRAM and SDRAM banks swapped	BMAP[1:0]=10 SDRAM bank 2 remapped
0x6000 0000 - 0x6FFF FFFF	NOR/PSRAM bank	SDRAM bank1	NOR/PSRAM bank
0x7000 0000 - 0x7FFF FFFF	SDRAM bank1	SDRAM bank2	SDRAM bank2
0x8000 0000 - 0x8FFF FFFF	NAND bank	NAND bank	NAND bank
0x9000 0000 - 0x9FFF FFFF	Reserved	Reserved	Reserved
0xC000 0000 - 0xCFFF FFFF	SDRAM bank1	NOR/PSRAM bank	SDRAM bank1
0xD000 0000 - 0xDFFF FFFF	SDRAM bank2	SDRAM bank2	SDRAM bank2

### 22.6.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory banks as shown in [Table 140](#).

**Table 140. NOR/PSRAM bank selection**

ADDR[27:26] <sup>(1)</sup>	Selected bank
00	Bank 1 - NOR/PSRAM 1
01	Bank 1 - NOR/PSRAM 2
10	Bank 1 - NOR/PSRAM 3
11	Bank 1 - NOR/PSRAM 4

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

**Table 141. NOR/PSRAM External memory address**

Memory width <sup>(1)</sup>	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	ADDR[25:0]	64 Mbytes x 8 = 512 Mbit
16-bit	ADDR[25:1] >> 1	64 Mbytes/2 x 16 = 512 Mbit
32-bit	ADDR[25:2] >> 2	64 Mbytes/4 x 32 = 512 Mbit

1. In case of a 16-bit external memory width, the FMC will internally use ADDR[25:1] to generate the address for external memory FMC\_A[24:0]. In case of a 32-bit memory width, the FMC will internally use ADDR[25:2] to generate the external address. Whatever the external memory width, FMC\_A[0] should be connected to external memory address A[0].

## 22.6.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in [Table 142](#).

**Table 142. NAND memory mapping and timing registers**

Start address	End address	FMC bank	Memory space	Timing register
0x8800 0000	0x8BFF FFFF	Bank 3 - NAND Flash	Attribute	FMC_PATT (0x8C)
0x8000 0000	0x83FF FFFF		Common	FMC_PMEM (0x88)

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in [Table 143](#) below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

**Table 143. NAND bank selection**

Section name	ADDR[17:16]	Address range
Address section	1X	0x020000-0x03FFFF
Command section	01	0x010000-0x01FFFF
Data section	00	0x000000-0x0FFFFF

The application software uses the 3 sections to access the NAND Flash memory:

- **To send a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

## 22.6.3 SDRAM address mapping

Two SDRAM banks are available as indicated in [Table 144](#).

**Table 144. SDRAM bank selection**

Selected bank	Control register	Timing register
SDRAM Bank1	FMC_SDCR1	FMC_SDTR1
SDRAM Bank2	FMC_SDCR2	FMC_SDTR2

[Table 145](#) shows SDRAM mapping for a 13-bit row and an 11-bit column configuration.

**Table 145. SDRAM address mapping**

Memory width <sup>(1)</sup>	Internal bank	Row address	Column address <sup>(2)</sup>	Maximum memory capacity (Mbytes)
8-bit	ADDR[25:24]	ADDR[23:11]	ADDR[10:0]	64 Mbytes: 4 x 8K x 2K
16-bit	ADDR[26:25]	ADDR[24:12]	ADDR[11:1]	128 Mbytes: 4 x 8K x 2K x 2
32-bit	ADDR[27:26]	ADDR[25:13]	ADDR[12:2]	256 Mbytes: 4 x 8K x 2K x 4

- When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC\_A[0] has to be connected to the external memory address A[0].
- The AutoPrecharge is not supported. FMC\_A[10] must be connected to the external memory address A[10] but it will be always driven low.

The ADDR[27:0] bits are translated into an external SDRAM address depending on the SDRAM controller configuration:

- Data size: 8, 16 or 32 bits
- Row size: 11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

**Table 146. SDRAM address mapping with 8-bit data bus width<sup>(1)(2)</sup>**

Row size configuration	ADDR(Internal Address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
11-bit row size configuration	Res.						Bank [1:0]	Row[10:0]										Column[7:0]									
	Res.					Bank [1:0]	Row[10:0]										Column[8:0]										
	Res.				Bank [1:0]	Row[10:0]										Column[9:0]											
	Res.			Bank [1:0]	Row[10:0]										Column[10:0]												
12-bit row size configuration	Res.						Bank [1:0]	Row[11:0]										Column[7:0]									
	Res.					Bank [1:0]	Row[11:0]										Column[8:0]										
	Res.				Bank [1:0]	Row[11:0]										Column[9:0]											
	Res.			Bank [1:0]	Row[11:0]										Column[10:0]												

**Table 146. SDRAM address mapping with 8-bit data bus width<sup>(1)(2)</sup> (continued)**

Row size configuration	ADDR(Internal Address Lines)																											
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
13-bit row size configuration	Res.				Bank [1:0]		Row[12:0]														Column[7:0]							
	Res.				Bank [1:0]		Row[12:0]														Column[8:0]							
	Res.			Bank [1:0]		Row[12:0]														Column[9:0]								
	Res.		Bank [1:0]		Row[12:0]														Column[10:0]									

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved (Res.) address range generates an AXI slave error.

**Table 147. SDRAM address mapping with 16-bit data bus width<sup>(1)(2)</sup>**

Row size Configuration	ADDR(address Lines)																												
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
11-bit row size configuration	Res.				Bank [1:0]		Row[10:0]														Column[7:0]								BM0 <sup>(3)</sup>
	Res.				Bank [1:0]		Row[10:0]														Column[8:0]								BM0
	Res.			Bank [1:0]		Row[10:0]														Column[9:0]								BM0	
	Res.		Bank [1:0]		Row[10:0]														Column[10:0]								BM0		
12-bit row size configuration	Res.				Bank [1:0]		Row[11:0]														Column[7:0]								BM0
	Res.				Bank [1:0]		Row[11:0]														Column[8:0]								BM0
	Res.			Bank [1:0]		Row[11:0]														Column[9:0]								BM0	
	Res.		Bank [1:0]		Row[11:0]														Column[10:0]								BM0		
13-bit row size configuration	Res.				Bank [1:0]		Row[12:0]														Column[7:0]								BM0
	Res.			Bank [1:0]		Row[12:0]														Column[8:0]								BM0	
	Res.		Bank [1:0]		Row[12:0]														Column[9:0]								BM0		
	Res.	Bank [1:0]	Row[12:0]														Column[10:0]								BM0				

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI Slave error.
3. BM0: is the byte mask for 16-bit access.

**Table 148. SDRAM address mapping with 32-bit data bus width<sup>(1)(2)</sup>**

Row size configuration	ADDR(address Lines)																															
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
11-bit row size configuration	Res.				Bank [1:0]		Row[10:0]												Column[7:0]							BM[1:0] <sup>(3)</sup>						
	Res.			Bank [1:0]		Row[10:0]												Column[8:0]							BM[1:0]							
	Res.		Bank [1:0]		Row[10:0]												Column[9:0]							BM[1:0]								
	Res.		Bank [1:0]		Row[10:0]												Column[10:0]							BM[1:0]								
12-bit row size configuration	Res.			Bank [1:0]		Row[11:0]												Column[7:0]							BM[1:0]							
	Res.		Bank [1:0]		Row[11:0]												Column[8:0]							BM[1:0]								
	Res.		Bank [1:0]		Row[11:0]												Column[9:0]							BM[1:0]								
	Res.		Bank [1:0]		Row[11:0]												Column[10:0]							BM[1:0]								
13-bit row size configuration	Res.			Bank [1:0]		Row[12:0]												Column[7:0]							BM[1:0]							
	Res.		Bank [1:0]		Row[12:0]												Column[8:0]							BM[1:0]								
	Res.		Bank [1:0]		Row[12:0]												Column[9:0]							BM[1:0]								
	Res.		Bank [1:0]		Row[12:0]												Column[10:0]							BM[1:0]								

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI slave error.
3. BM[1:0]: is the byte mask for 32-bit access.

## 22.7 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC\_CLK) output.

The FMC output Clock (FMC\_CLK) is a sub-multiple of the `fmc_ker_ck` clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC\_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC\_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC\_CLK continuous clock, Bank 1 must be configured in synchronous mode (see [Section 22.7.6: NOR/PSRAM controller registers](#)). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID) otherwise the FMC\_CLK frequency will be changed depending on AXI data transaction (refer to [Section 22.7.5: Synchronous transactions](#) for FMC\_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see [Section 22.7.6: NOR/PSRAM controller registers](#)).

The programmable memory parameters include access times (see [Table 149](#)) and support for wait management (for PSRAM and NOR Flash memory accessed in burst mode).

**Table 149. Programmable NOR/PSRAM access parameters**

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	FMC clock cycle ( <code>fmc_ker_ck</code> )	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	FMC clock cycle ( <code>fmc_ker_ck</code> )	1	15
Data setup	Duration of the data setup phase	Asynchronous	FMC clock cycle ( <code>fmc_ker_ck</code> )	1	256
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read	FMC clock cycle ( <code>fmc_ker_ck</code> )	0	15
Clock divide ratio	Number of FMC clock cycles ( <code>fmc_ker_ck</code> ) to build one memory clock cycle (CLK)	Synchronous	FMC clock cycle ( <code>fmc_ker_ck</code> )	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle ( <code>fmc_ker_ck</code> )	2	17

### 22.7.1 External memory interface signals

Table 150, Table 151 and Table 152 list the signals that are typically used to interface with NOR Flash memory, SRAM and PSRAM.

Note: The prefix “N” identifies the signals which are active low.

#### NOR Flash memory, non-multiplexed I/Os

**Table 150. Non-multiplexed I/O NOR Flash memory**

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Bidirectional data bus
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR Flash devices)
NWAIT	I	NOR Flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

#### NOR Flash memory, 16-bit multiplexed I/Os

**Table 151. 16-bit multiplexed I/O NOR Flash memory**

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR Flash devices)
NWAIT	I	NOR Flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

**PSRAM/SRAM, non-multiplexed I/Os****Table 152. Non-multiplexed I/Os PSRAM/SRAM**

FMC signal name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Data bidirectional bus
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[3:0]	O	Byte lane output. Byte 0 to Byte 3 control (Upper and lower byte enable)

The maximum capacity is 512 Mbits.

**PSRAM, 16-bit multiplexed I/Os****Table 153. 16-Bit multiplexed I/O PSRAM**

FMC signal name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

### 22.7.2 Supported memories and transactions

Table 154 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR Flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

**Table 154. NOR Flash/PSRAM: Example of supported memories and transactions<sup>(1)</sup>**

Device	Mode	R/W	AXI data size	Memory data size	Allowed/not allowed	Comments
NOR Flash (muxed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	N	
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	
	Synchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Synchronous	W	16/32/64	16	Y	

**Table 154. NOR Flash/PSRAM: Example of supported memories and transactions<sup>(1)</sup>**

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
SRAM and ROM	Asynchronous	R	8/16	16	Y	
	Asynchronous	W	8/16	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses Use of byte lanes NBL[1:0]
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses Use of byte lanes NBL[1:0]

1. NBL[1:0] are also driven by AXI write strobes.

### 22.7.3 General timing rules

Signal synchronization is performed as follows:

- All controller output signals change on the rising edge of the `fmc_ker_ck` clock.
- In synchronous read and write modes, all output signals change on the rising edge of `fmc_ker_ck` clock. Whatever the `CLKDIV` value, all outputs change as follows:
  - `NOEL/NWEL/ NEL/NADV L/ NADV H /NBLL/` Address valid outputs change on the falling edge of `FMC_CLK` clock.
  - `NOEH/ NWEH / NEH/ NOEH/NBLH/` Address invalid outputs change on the rising edge of `FMC_CLK` clock.

### 22.7.4 NOR Flash/PSRAM controller asynchronous transactions

Asynchronous transactions on static memories (NOR Flash memory, PSRAM, SRAM) are performed as follows:

- Signals are synchronized by the internal clock. This clock is not issued to the memory.
- The FMC always samples the data before de-asserting the Chip Select signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the extended mode is enabled (`EXTMOD` bit is set in the `FMC_BCRx` register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the extended mode is disabled (`EXTMOD` bit is reset in the `FMC_BCRx` register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (`MTYP = 0x0` or `0x01` in the `FMC_BCRx` register)
  - Mode 2 is the default mode when NOR memory type is selected (`MTYP = 0x10` in the `FMC_BCRx` register).

**Mode 1 - SRAM/PSRAM (CRAM)**

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC\_BCRx, and FMC\_BTRx/FMC\_BWTRx registers.

**Figure 88. Mode 1 read access waveforms**

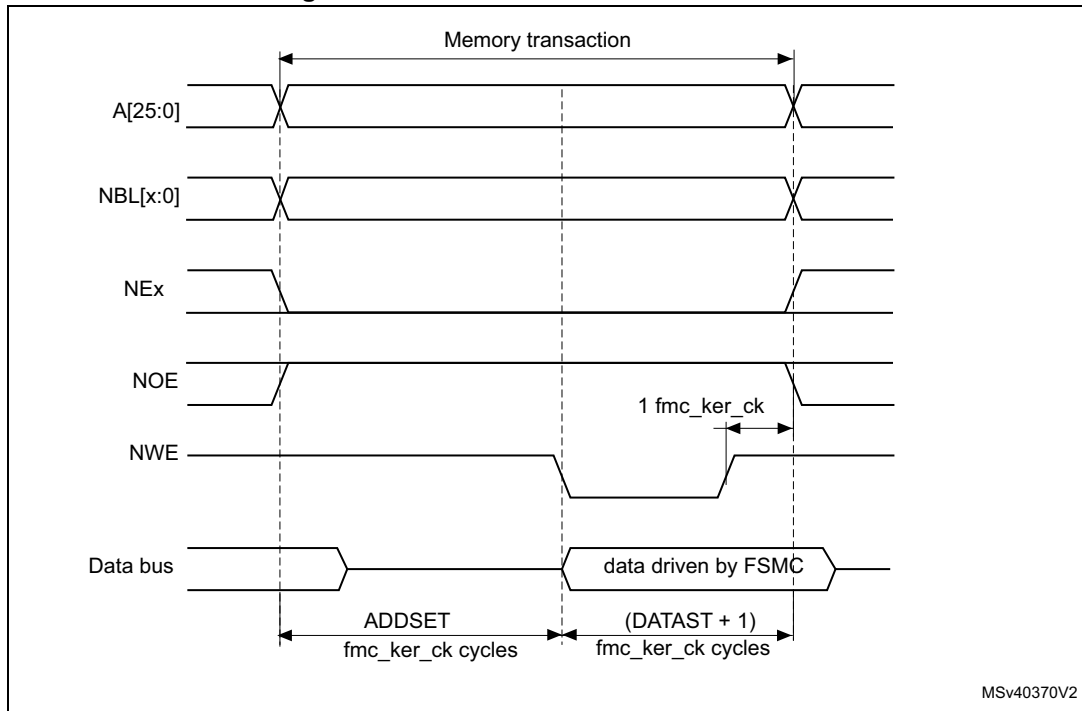

Figure 89. Mode 1 write access waveforms

The `fmc_ker_ck` cycle at the end of the write transaction helps guarantee the address and data hold time after the `NWE` rising edge. Due to the presence of this `fmc_ker_ck` cycle, the `DATAST` value must be greater than zero ( $DATAST > 0$ ).

Table 155. FMC\_BCRx bit fields

Bit number	Bit name	Value to set
31	FMCEN	0x0
30-26	Reserved	0x000
25-24	BMAP	As needed
23-22	Reserved	0x000
21	WFDIS	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in asynchronous mode)
18:16	CPSIZE	0x0 (no effect in asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in asynchronous mode)
12	WREN	As needed
11	WAITCFG	Don't care
10	Reserved	0x0

Table 155. FMC\_BCRx bit fields (continued)

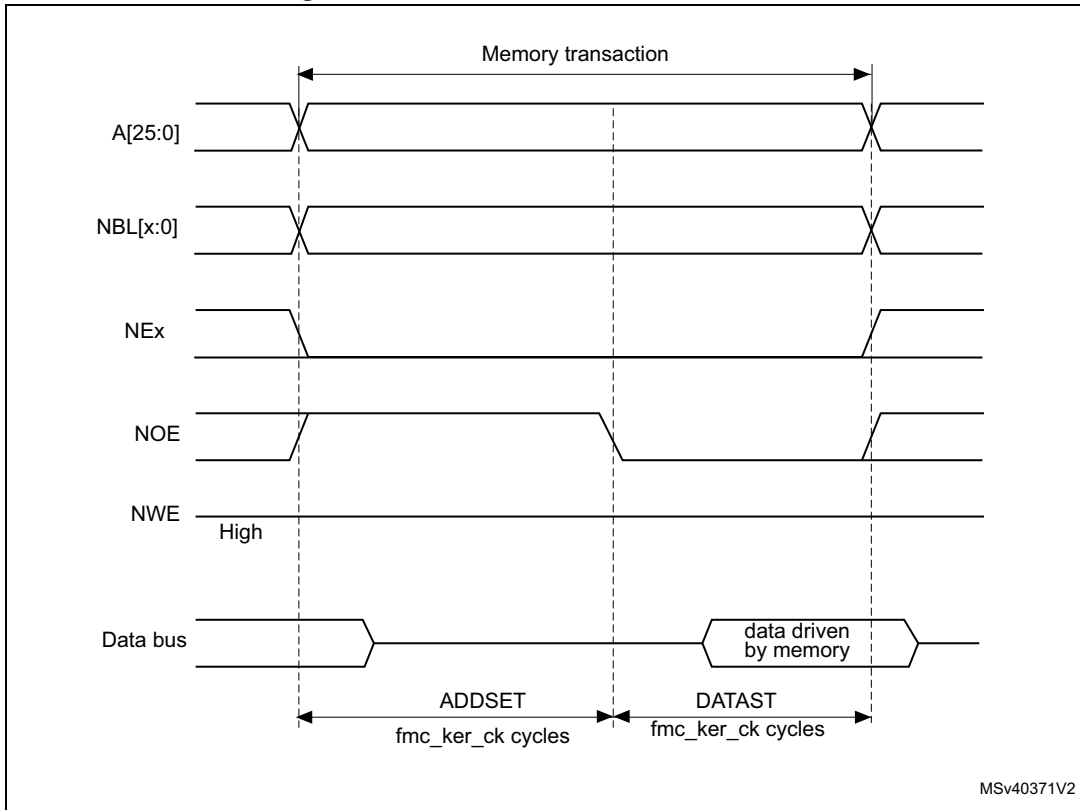

Bit number	Bit name	Value to set
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1
6	FACCEN	Don't care
5-4	MWID	As needed
3-2	MTYP	As needed, exclude 0x2 (NOR Flash memory)
1	MUXE	0x0

### WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC\_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc\_ker\_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$\text{DATAST} \geq (4 \times \text{FMC\_CLK}) + \text{max\_wait\_assertion\_time}$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):  
if

$$\text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}$$

then:

$$\text{DATAST} \geq (4 \times \text{FMC\_CLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase})$$

otherwise

$$\text{DATAST} \geq (4 \times \text{FMC\_CLK})$$

where max\_wait\_assertion\_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

[Figure 101](#) and [Figure 102](#) show the number of fmc\_ker\_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 101. Asynchronous wait during a read access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC\_BCRx register.

Figure 102. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC\_BCRx register.

### 22.7.5 Synchronous transactions

The memory clock, FMC\_CLK, is a sub-multiple of fmc\_ker\_ck. It depends on the value of CLKDIV and the MWID/ AXI data size, following the formula given below:

$$\text{FMC\_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AXI data size}))$$

If MWID is 16 or 8-bit, the FMC\_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32-bit, the FMC\_CLK divider ratio depends also on AXI data size.

Example:

- If CLKDIV=1, MWID = 32 bits, AXI data size=8 bits, FMC\_CLK=fmc\_ker\_ck/4.
- If CLKDIV=1, MWID = 16 bits, AXI data size=8 bits, FMC\_CLK=fmc\_ker\_ck/2.

NOR Flash memories specify a minimum time from NADV assertion to FMC\_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

For some PSRAM memories which must be configured to synchronous mode, during the BCR register writing, the memory attribute space must be configured to device or strongly-ordered. Once PSRAM BCR register is configured, the memory attribute of PSRAM address space can be programmed to cacheable.

#### Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) FMC\_CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) FMC\_CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

### Single-burst transfer

When the selected bank is configured in burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and de-assert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

### Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC\_BCR1 register following the memory page size.

### Wait management

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC\_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR Flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC\_BCRx registers (x = 0..3).

Figure 103. Wait configuration waveforms

Bit 31 **FMCEN**: FMC controller Enable

This bit enables/disables the FMC controller.

0: Disable the FMC controller

1: Enable the FMC controller

*Note: The FMCEN bit of the FMC\_BCR2..4 registers is don't care. It is only enabled through the FMC\_BCR1 register.*

Bits 31: 22 Reserved, must be kept at reset value

Bits 25: 24 **BMAP[1:0]**: FMC bank mapping

These bits allows different to remap SDRAM bank2 or swap the FMC NOR/PSRAM and SDRAM banks. Refer to Table 10 for

01: Default mapping (Refer to Figure 2 and Table 10).

10: NOR/PSRAM bank and SDRAM bank 1/bank2 are swapped.

11: SDRAM Bank2 remapped on FMC bank2 and still accessible at default mapping

12: reserved.

*Note: The BMAP bits of the FMC\_BCR2..4 registers are don't care. It is only enabled through the FMC\_BCR1 register.*

Bits 23: 22 Reserved, must be kept at reset value

Bit 21 **WFDIS**: Write FIFO Disable

This bit disables the Write FIFO used by the FMC controller.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

*Note: The WFDIS bit of the FMC\_BCR2..4 registers is don't care. It is only enabled through the FMC\_BCR1 register.*

Bit 20 **CCLKEN**: Continuous Clock Enable

This bit enables the FMC\_CLK clock output to external memory devices.

0: The FMC\_CLK is only generated during the synchronous memory access (read/write transaction). The FMC\_CLK clock ratio is specified by the programmed CLKDIV value in the FMC\_BCRx register (default after reset).

1: The FMC\_CLK is generated continuously during asynchronous and synchronous access. The FMC\_CLK clock is activated when the CCLKEN is set.

*Note: The CCLKEN bit of the FMC\_BCR2..4 registers is don't care. It is only enabled through the FMC\_BCR1 register. Bank 1 must be configured in synchronous mode to generate the FMC\_CLK continuous clock.*

*If CCLKEN bit is set, the FMC\_CLK clock ratio is specified by CLKDIV value in the FMC\_BTR1 register. CLKDIV in FMC\_BWTR1 is don't care.*

*If the synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC\_BTR2..4 and FMC\_BWTR2..4 registers for other banks has no effect.)*

Bit 19 **CBURSTRW**: Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC\_BCRx register.

0: Write operations are always performed in asynchronous mode

1: Write operations are performed in synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM Page Size

These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset).

001: 128 bytes

010: 256 bytes

100: 1024 bytes

Other configuration: reserved.

Bit 15 **ASYNCAWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)

1: NWAIT signal is taken in to account when running an asynchronous protocol

Bit 14 **EXTMOD**: Extended mode enable.

This bit enables the FMC to program the write timings for asynchronous accesses inside the FMC\_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC\_BWTR register are not taken into account (default after reset)

1: values inside FMC\_BWTR register are taken into account

*Note: When the extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:*

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).*

- Bit 13 **WAITEN**: Wait enable bit  
This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in synchronous mode.  
0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period)  
1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)
- Bit 12 **WREN**: Write enable bit  
This bit indicates whether write operations are enabled/disabled in the bank by the FMC:  
0: Write operations are disabled in the bank by the FMC, an AXI slave error is reported,  
1: Write operations are enabled for the bank by the FMC (default after reset).
- Bit 11 **WAITCFG**: Wait timing configuration  
The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:  
0: NWAIT signal is active one data cycle before wait state (default after reset),  
1: NWAIT signal is active during wait state (not used for PSRAM).
- Bit 10 Reserved, must be kept at reset value
- Bit 9 **WAITPOL**: Wait signal polarity bit  
This bit defines the polarity of the wait signal from memory used for either in synchronous or asynchronous mode:  
0: NWAIT active low (default after reset),  
1: NWAIT active high.
- Bit 8 **BURSTEN**: Burst enable bit  
This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:  
0: Burst mode disabled (default after reset). Read accesses are performed in asynchronous mode.  
1: Burst mode enable. Read accesses are performed in synchronous mode.
- Bit 7 Reserved, must be kept at reset value
- Bit 6 **FACCEN**: Flash access enable  
This bit enables NOR Flash memory access operations.  
0: Corresponding NOR Flash memory access is disabled  
1: Corresponding NOR Flash memory access is enabled (default after reset)
- Bits 5:4 **MWID[1:0]**: Memory data bus width  
Defines the external memory device width, valid for all type of memories.  
00: 8 bits  
01: 16 bits (default after reset)  
10: 32 bits  
11: reserved

**Bits 3:2 MTYP[1:0]:** Memory type

These bits define the type of external memory attached to the corresponding memory bank:

00: SRAM (default after reset for Bank 2...4)

01: PSRAM (CRAM)

10: NOR Flash/OneNAND Flash (default after reset for Bank 1)

11: reserved

**Bit 1 MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:

0: Address/Data non-multiplexed

1: Address/Data multiplexed on databus (default after reset)

**Bit 0 MBKEN:** Memory bank enable bit

This bit enables the memory bank. After reset Bank1 is enabled, all others are disabled.

Accessing a disabled bank causes an ERROR on AXI bus.

0: Corresponding memory bank is disabled

1: Corresponding memory bank is enabled

**SRAM/NOR-Flash chip-select timing registers 1..4 (FMC\_BTR1..4)**

Address offset: 0x04 + 8 \* (x - 1), x = 1..4

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories. If the EXTMOD bit is set in the FMC\_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC\_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD		DATLAT				CLKDIV				BUSTURN			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST								ADDHLD				ADDSET			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value

Bits 29:28 **ACCMOD[1:0]**: Access mode

These bits specify the asynchronous access modes as shown in the timing diagrams. They are taken into account only when the EXTMOD bit in the FMC\_BCRx register is 1.

- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:24 **DATLAT[3:0]**: (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in fmc\_ker\_ck periods, but in FMC\_CLK periods. For asynchronous access, this value is don't care.

- 0000: Data latency of 2 FMC\_CLK clock cycles for first burst access
- 1111: Data latency of 17 FMC\_CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FMC\_CLK signal)

These bits define the period of FMC\_CLK clock output signal, expressed in number of fmc\_ker\_ck cycles:

- 0000: Reserved
- 0001: FMC\_CLK period = 2 × fmc\_ker\_ck periods
- 0010: FMC\_CLK period = 3 × fmc\_ker\_ck periods
- 1111: FMC\_CLK period = 16 × fmc\_ker\_ck periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don't care.

Note: Refer to [Section 22.7.5: Synchronous transactions](#) for FMC\_CLK divider ratio formula)

Bits 19:16 **BUSTURN**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions ( $t_{EHEL}$  from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access ( $t_{EHQZ}$ ). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous /synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for modes muxed and D.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - Two consecutive asynchronous read transfers to the same static memory bank except for modes muxed and D.
  - An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for modes muxed and D.
  - An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read).
  - Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc\_ker\_ck clock cycle added

...

1111: BUSTURN phase duration = 15 x fmc\_ker\_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST**: Data-phase duration

These bits are written by software to define the duration of the data phase (refer to [Figure 88](#) to [Figure 100](#)), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 x fmc\_ker\_ck clock cycles

0000 0010: DATAST phase duration = 2 x fmc\_ker\_ck clock cycles

...

1111 1111: DATAST phase duration = 255 x fmc\_ker\_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, please refer to the respective figure ([Figure 88](#) to [Figure 100](#)).

Example: Mode1, write access, DATAST = 1: Data-phase duration = DATAST+1 = 1 x fmc\_ker\_ck clock cycles.

*Note: In synchronous accesses, this value is don't care.*

Bits 7:4 **ADDHLD**: Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 88](#) to [Figure 100](#)), used in mode D or multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration =  $1 \times \text{fmc\_ker\_ck}$  clock cycle

0010: ADDHLD phase duration =  $2 \times \text{fmc\_ker\_ck}$  clock cycle

...

1111: ADDHLD phase duration =  $15 \times \text{fmc\_ker\_ck}$  clock cycles (default value after reset)

For each access mode address-hold phase duration, please refer to the respective figure ([Figure 88](#) to [Figure 100](#)).

*Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.*

Bits 3:0 **ADDSET**: Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to [Figure 88](#) to [Figure 100](#)), used in SRAMs, ROMs and asynchronous NOR Flash:

0000: ADDSET phase duration =  $0 \times \text{fmc\_ker\_ck}$  clock cycle

...

1111: ADDSET phase duration =  $15 \times \text{fmc\_ker\_ck}$  clock cycles (default value after reset)

For each access mode address setup phase duration, please refer to the respective figure (refer to [Figure 88](#) to [Figure 100](#)).

*Note: In synchronous accesses, this value is don't care.*

*In Muxed mode or Mode D, the minimum value for ADDSET is 1.*

*Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.*

*On PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.*

*This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).*

### SRAM/NOR-Flash write timing registers 1..4 (FMC\_BWTR1..4)

Address offset:  $0x104 + 8 * (x - 1)$ ,  $x = 1...4$

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC\_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSTURN			
		rw	rw									rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST								ADDHLD				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value

Bits 29:28 **ACCMOD**: Access mode.

These bits specify the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC\_BCRx register is 1.

- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:20 Reserved, must be kept at reset value

Bits 19:16 **BUSTURN**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write transaction to match the minimum time between consecutive transactions ( $t_{EHEL}$  from ENx high to ENx low):

$$(BUSTURN + 1) \text{ fmc\_ker\_ck period} \geq t_{EHELmin}$$

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different expect for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for modes muxed and D.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc\_ker\_ck clock cycle added

...

1111: BUSTURN phase duration = 15 fmc\_ker\_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST**: Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to [Figure 88](#) to [Figure 100](#)), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration =  $1 \times \text{fmc\_ker\_ck}$  clock cycles

0000 0010: DATAST phase duration =  $2 \times \text{fmc\_ker\_ck}$  clock cycles

...

1111 1111: DATAST phase duration =  $255 \times \text{fmc\_ker\_ck}$  clock cycles (default value after reset)

Bits 7:4 **ADDHLD**: Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 88](#) to [Figure 100](#)), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration =  $1 \times \text{fmc\_ker\_ck}$  clock cycle

0010: ADDHLD phase duration =  $2 \times \text{fmc\_ker\_ck}$  clock cycle

...

1111: ADDHLD phase duration =  $15 \times \text{fmc\_ker\_ck}$  clock cycles (default value after reset)

*Note: In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.*

Bits 3:0 **ADDSET**: Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in  $\text{fmc\_ker\_ck}$  cycles (refer to [Figure 88](#) to [Figure 100](#)), used in asynchronous accesses:

0000: ADDSET phase duration =  $0 \times \text{fmc\_ker\_ck}$  clock cycle

...

1111: ADDSET phase duration =  $15 \times \text{fmc\_ker\_ck}$  clock cycles (default value after reset)

*Note: In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.*

## 22.8 NAND Flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND Flash memories.

The NAND bank is configured through dedicated registers ([Section 22.8.7](#)). The programmable memory parameters include access timings (shown in [Table 175](#)) and ECC configuration.

**Table 175. Programmable NAND Flash access parameters**

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (fmc_ker_ck) required to set up the address before the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	255
Memory wait	Minimum duration (in fmc_ker_ck clock cycles) of the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	2	255
Memory hold	Number of clock cycles (fmc_ker_ck) during which the address must be held (as well as the data if a write access is performed) after the command de-assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	254
Memory databus high-Z	Number of clock cycles (fmc_ker_ck) during which the data bus is kept in high-Z state after a write access has started	Write	AHB clock cycle (fmc_ker_ck)	0	254

### 22.8.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND Flash memories.

*Note:* The prefix "N" identifies the signals which are active low.

#### 8-bit NAND Flash memory

**Table 176. 8-bit NAND Flash memory**

FMC signal name	I/O	Function
A[17]	O	NAND Flash address latch enable (ALE) signal
A[16]	O	NAND Flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND Flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

**16-bit NAND Flash memory**

**Table 177. 16-bit NAND Flash memory**

FMC signal name	I/O	Function
A[17]	O	NAND Flash address latch enable (ALE) signal
A[16]	O	NAND Flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND Flash ready/busy input signal to the FMC

*Note:* Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

**22.8.2 NAND Flash supported memories and transactions**

Table 178 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND Flash controller are shown in gray.

**Table 178. Supported memories and transactions**

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	-
	Asynchronous	W	8	8	Y	-
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses
	Asynchronous	R	32	8	Y	Split into 8 FMC accesses
	Asynchronous	W	32	8	Y	Split into 8 FMC accesses

Table 178. Supported memories and transactions (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	32	16	Y	Split into 4 FMC accesses
	Asynchronous	W	32	16	Y	Split into 4 FMC accesses

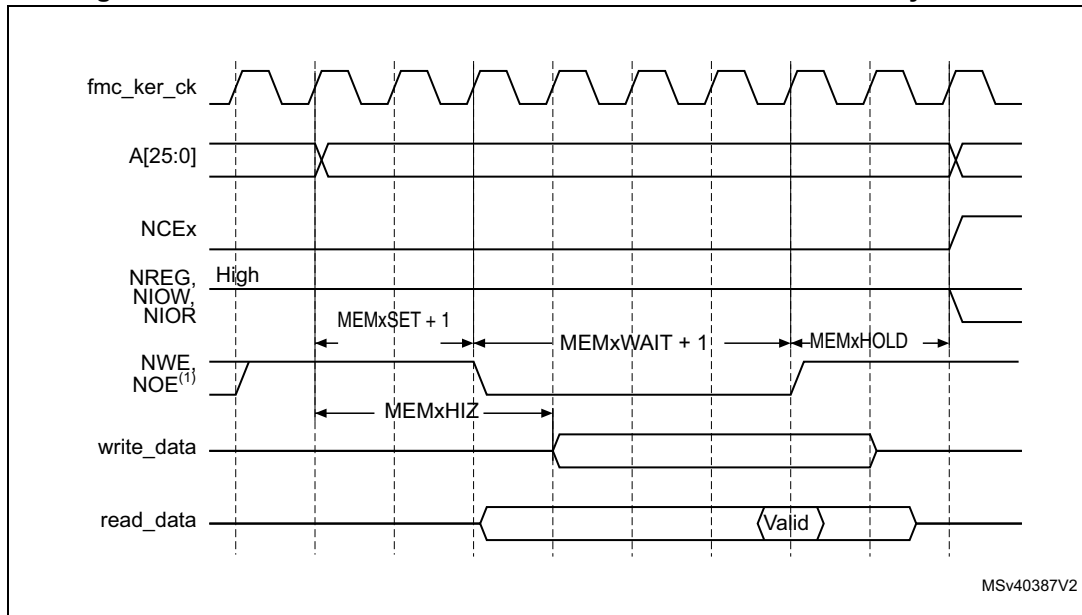

### 22.8.3 Timing diagrams for NAND Flash memories

The NAND Flash memory bank is managed through a set of registers:

- Control register: FMC\_PCR
- Interrupt status register: FMC\_SR
- ECC register: FMC\_ECCR
- Timing register for Common memory space: FMC\_PMEM
- Timing register for Attribute memory space: FMC\_PATT

Each timing configuration register contains three parameters used to define the number of `fmc_ker_ck` cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. [Figure 106](#) shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 106. NAND Flash controller waveforms for common memory access

1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write accesses, the hold phase delay is (MEMHOLD) fmc\_ker\_ck cycles and for read access is (MEMHOLD + 1) fmc\_ker\_ck cycles.

## 22.8.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC\_PCR and FMC\_PMEM (and for some devices, FMC\_PATT, see [Section 22.8.5: NAND Flash prewait feature](#)) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash memory, PWAITEN = 0 or 1 as needed, see [Section 22.6.2: NAND Flash memory address mapping](#) for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used

to implement the prewait functionality needed by some NAND Flash memories (see details in [Section 22.8.5: NAND Flash prewait feature](#)).

4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.
6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
  - by simply performing the operation described in step 5
  - a new random address can be accessed by restarting the operation at step 3
  - a new command can be sent to the NAND Flash device by restarting at step 2

### 22.8.5 NAND Flash prewait feature

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see [Figure 107](#)).

**Figure 107. Access to non ‘CE don’t care’ NAND-Flash**

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x8802 0000: FMC performs a write access using FMC\_PATT2 timing definition, where  $ATTHOLD \geq 7$  (providing that  $(7+1) \times fmc\_ker\_ck = 112\text{ ns} > t_{WB\text{ max}}$ ). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don't care).

When this function is required, it can be performed by programming the MEMHOLD value to meet the  $t_{\text{WB}}$  timing. However, any CPU read access to NAND Flash memory has a hold delay of  $(\text{MEMHOLD} + 1) \text{fmc\_ker\_ck}$  cycles, and any CPU write access has a hold delay of  $(\text{MEMHOLD}) \text{fmc\_ker\_ck}$  cycles that is inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the  $t_{\text{WB}}$  timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

### 22.8.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC controller includes an error correction code computation hardware block. It reduces the host CPU workload when processing the ECC by software. The ECC block is associated with NAND bank.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND Flash memory. It is based on the BCH8 coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash bank, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC\_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to one in the FMC\_PCR registers.

Execute below the sequence to perform an ECC computation:

1. Enable the ECCEN bit in the FMC\_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Wait until the ECC code is ready (FIFO empty).
4. Read the ECC value available in the FMC\_ECCR register and store it in a variable.
5. Clear the ECCEN bit and then enable it in the FMC\_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
6. Read the new ECC value available in the FMC\_ECCR register.
7. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 22.8.7 NAND Flash controller registers

#### NAND Flash control registers (FMC\_PCR)

Address offset: 0x80

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCPS			TAR				TCLR				Res.	Res.	ECCEN	PWID		Res.	PBKEN	PWAITEN	Res.
												rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW			rW	rW	rW		rW	rW	

Bits 31:20 Reserved, must be kept at reset value

Bits 19:17 **ECCPS**: ECC page size.

These bits define the page size for the extended ECC:

000: 256 bytes

001: 512 bytes

010: 1024 bytes

011: 2048 bytes

100: 4096 bytes

101: 8192 bytes

Bits 16:13 **TAR**: ALE to RE delay.

These bits set time from ALE low to RE low in number of fmc\_ker\_ck clock cycles.

Time is:  $t_{ar} = (TAR + SET + 2) \times t_{fmc\_ker\_ck}$  where  $t_{fmc\_ker\_ck}$  is the FMC clock period

0000: 1 x fmc\_ker\_ck cycle (default)

1111: 16 x fmc\_ker\_ck cycles

*Note: Set is MEMSET or ATTSET according to the addressed space.*

Bits 12:9 **TCLR**: CLE to RE delay.

These bits set time from CLE low to RE low in number of `fmc_ker_ck` clock cycles. The time is give by the following formula:

$t_{clr} = (TCLR + SET + 2) \times t_{fmc\_ker\_ck}$  where  $t_{fmc\_ker\_ck}$  is the `fmc_ker_ck` clock period

0000: 1 x `fmc_ker_ck` cycle (default)

1111: 16 x `fmc_ker_ck` cycles

*Note: Set is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value

Bit 6 **ECCEN**: ECC computation logic enable bit

0: ECC logic is disabled and reset (default after reset),

1: ECC logic is enabled.

Bits 5:4 **PWID**: Data bus width.

These bits define the external memory device width.

00: 8 bits

01: 16 bits (default after reset).

10: reserved.

11: reserved.

Bit 3 Reserved, must be kept at reset value

Bit 2 **PBKEN**: NAND Flash memory bank enable bit.

This bit enables the memory bank. Accessing a disabled memory bank causes an ERROR on AXI bus

0: Corresponding memory bank is disabled (default after reset)

1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit.

This bit enables the Wait feature for the NAND Flash memory bank:

0: disabled

1: enabled

Bit 0 Reserved, must be kept at reset value

## FIFO status and interrupt register (FMC\_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data.

This is used to quickly write to the FIFO and free the AXI bus for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FEMPT	IFEN	ILEN	IREN	IFS	ILS	IRS
									r	rw	rw	rw	rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value

- Bit 6 **FEMPT**: FIFO empty.  
Read-only bit that provides the status of the FIFO  
0: FIFO not empty  
1: FIFO empty
- Bit 5 **IFEN**: Interrupt falling edge detection enable bit  
0: Interrupt falling edge detection request disabled  
1: Interrupt falling edge detection request enabled
- Bit 4 **ILEN**: Interrupt high-level detection enable bit  
0: Interrupt high-level detection request disabled  
1: Interrupt high-level detection request enabled
- Bit 3 **IREN**: Interrupt rising edge detection enable bit  
0: Interrupt rising edge detection request disabled  
1: Interrupt rising edge detection request enabled
- Bit 2 **IFS**: Interrupt falling edge status  
The flag is set by hardware and reset by software.  
0: No interrupt falling edge occurred  
1: Interrupt falling edge occurred  
*Note: If this bit is written by software to 1 it will be set.*
- Bit 1 **ILS**: Interrupt high-level status  
The flag is set by hardware and reset by software.  
0: No Interrupt high-level occurred  
1: Interrupt high-level occurred
- Bit 0 **IRS**: Interrupt rising edge status  
The flag is set by hardware and reset by software.  
0: No interrupt rising edge occurred  
1: Interrupt rising edge occurred  
*Note: If this bit is written by software to 1 it will be set.*

**Common memory space timing register 2..4 (FMC\_PMEM)**

Address offset: Address: 0x88

Reset value: 0xFCFC FCFC

The FMC\_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEMHIZx								MEMHOLDx							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEMWAITx								MEMSETx							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ**: Common memory x data bus Hi-Z time

These bits define the number of fmc\_ker\_ck clock cycles during which the data bus is kept Hi-Z after the start of a NAND Flash write access to common memory space. This is only valid for write transactions:

- 0000 0000: 0 x fmc\_ker\_ck cycle
- 1111 1110: 254 x fmc\_ker\_ck cycles
- 1111 1111: reserved.

Bits 23:16 **MEMHOLD**: Common memory hold time

These bits define the number of fmc\_ker\_ck clock cycles for write accesses and fmc\_ker\_ck+1 clock cycles for read accesses during which the address is held (and data for write accesses) after the command is de-asserted (NWE, NOE), for NAND Flash read or write access to common memory space:

- 0000 0000: reserved.
- 0000 0001: 1 fmc\_ker\_ck cycle for write access / 3 fmc\_ker\_ck cycle for read access
- 1111 1110: 254 fmc\_ker\_ck cycles for write access / 257 fmc\_ker\_ck cycles for read access
- 1111 1111: reserved.

Bits 15:8 **MEMWAIT**: Common memory wait time

These bits define the minimum number of fmc\_ker\_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to common memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc\_ker\_ck:

- 0000 0000: reserved
- 0000 0001: x fmc\_ker\_ck cycles (+ wait cycle introduced by de-asserting NWAIT)
- 1111 1110: 255 x fmc\_ker\_ck cycles (+ wait cycle introduced by de-asserting NWAIT)
- 1111 1111: reserved.

Bits 7:0 **MEMSET**: Common memory x setup time

These bits define the number of fmc\_ker\_ck (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND Flash read or write access to common memory space:

- 0000 0000: fmc\_ker\_ck cycles
- 1111 1110: 255 x fmc\_ker\_ck cycles
- 1111 1111: reserved

**Attribute memory space timing registers (FMC\_PATT)**

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC\_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to [Section 22.8.5: NAND Flash prewait feature](#)).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ								ATTHOLD							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ATTWAIT								ATTSET							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

**Bits 31:24 ATTHIZx:** Attribute memory data bus Hi-Z time

These bits define the number of fmc\_ker\_ck clock cycles during which the data bus is kept in Hi-Z after the start of a NAND Flash write access to attribute memory space on socket. Only valid for writ transaction:

- 0000 0000: 0 x fmc\_ker\_ck cycle
- 1111 1110: 254 x fmc\_ker\_ck cycles
- 1111 1111: reserved.

**Bits 23:16 ATTHOLD:** Attribute memory hold time

These bits define the number of fmc\_ker\_ck clock cycles during which the address is held (and data for write access) after the command de-assertion (NWE, NOE), for NAND Flash read or write access to attribute memory space:

- 0000 0000: reserved
- 0000 0001: 1 x fmc\_ker\_ck cycle
- 1111 1110: 254 x fmc\_ker\_ck cycles
- 1111 1111: reserved.

**Bits 15:8 ATTWAIT:** Attribute memory wait time

These bits define the minimum number of x fmc\_ker\_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to attribute memory space. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc\_ker\_ck:

- 0000 0000: reserved
- 0000 0001: 2 x fmc\_ker\_ck cycles (+ wait cycle introduced by de-assertion of NWAIT)
- 1111 1110: 255 x fmc\_ker\_ck cycles (+ wait cycle introduced by de-asserting NWAIT)
- 1111 1111: reserved.

**Bits 7:0 ATTSET:** Attribute memory setup time

These bits define the number of fmc\_ker\_ck (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND Flash read or write access to attribute memory space:

- 0000 0000: 1 x fmc\_ker\_ck cycle
- 1111 1110: 255 x fmc\_ker\_ck cycles
- 1111 1111: reserved.

**ECC result registers (FMC\_ECCR)**

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads/writes the data from a NAND Flash memory page at the correct address (refer to [Section 22.8.6: Computation of the error correction code \(ECC\) in NAND Flash memory](#)), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC\_PCR registers), the CPU must read the computed ECC value from the FMC\_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC\_ECCR register should be cleared after being read by setting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to '1'.

Bits 31:0 **ECC**: ECC result

This field contains the value computed by the ECC computation logic. [Table 179](#) describes the contents of these bit fields.

**Table 179. ECC result relevant bits**

ECCPS[2:0]	Page size in bytes	ECC bits
000	256	ECC[21:0]
001	512	ECC[23:0]
010	1024	ECC[25:0]
011	2048	ECC[27:0]
100	4096	ECC[29:0]
101	8192	ECC[31:0]

## 22.9 SDRAM controller

### 22.9.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be  $fmc\_ker\_ck/2$  or  $fmc\_ker\_ck/3$
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

### 22.9.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must be configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

**Table 180. SDRAM signals**

SDRAM signal	I/O type	Description	Alternate function
SDCLK	O	SDRAM clock	-
SDCKE[1:0]	O	SDCKE0: SDRAM Bank 1 Clock Enable SDCKE1: SDRAM Bank 2 Clock Enable	-
SDNE[1:0]	O	SDNE0: SDRAM Bank 1 Chip Enable SDNE1: SDRAM Bank 2 Chip Enable	-
A[12:0]	O	Address	FMC_A[12:0]
D[31:0]	I/O	Bidirectional data bus	FMC_D[31:0]
BA[1:0]	O	Bank Address	FMC_A[15:14]
NRAS	O	Row Address Strobe	-
NCAS	O	Column Address Strobe	-
SDNWE	O	Write Enable	-
NBL[3:0]	O	Output Byte Mask for write accesses (memory signal name: DQM[3:0])	FMC_NBL[3:0]

### 22.9.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC\_SDCLK).

#### SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1 and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC\_SDCMR register:

1. Program the memory device features into the FMC\_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC\_SDCR1 register.
2. Program the memory device timing into the FMC\_SDTRx register. The TRP and TRC timings must be programmed in the FMC\_SDTR1 register.
3. Set MODE bits to '001' and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100  $\mu$ s (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to '010' and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to issue a "Precharge All" command.
6. Set MODE bits to '011', and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC\_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field, set the MODE bits to '100', and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to issue a "Load Mode Register" command and program the SDRAM device. In particular the Burst Length (BL) has to be set to '1' and the CAS latency has to be selected. If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank and the Target Bank bits set accordingly. For mobile SDRAM devices, the MRD field is also used to configure the extended mode register while issuing the Load Mode Register"
8. Program the refresh rate in the FMC\_SDRTR register  
The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefore the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR Flash/PSRAM/SRAM or NAND Flash controller.

*Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD and TRAS timings) in the FMC\_SDTR1 register.*

### SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC\_SDCRx register.

Figure 108. Burst write SDRAM access waveforms

The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

### SDRAM controller read cycle

The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

**Figure 109. Burst read SDRAM access**

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period (up to 3 memory clock cycles, programmed FMC\_SDCRx) and during the RPIPE delay when set to 2xfmc\_ker\_ck clock cycles as configured in FMC\_SDCR1) following this formula: CAS Latency + 1 + (RPIPE DIV2). The RBURST bit must be set in the FMC\_SDCR1 register to anticipate the next read access.

Examples:

- CAS=3, RPIPE= 2xfmc\_ker\_ck. In this case, 5 data (not committed) are stored in the FIFO (4 data during CAS latency and 1 data during RPIPE delay)
- CAS=3, RPIPE= 1xfmc\_ker\_ck. In this case, 4 data (not committed) are stored in the FIFO (4 data during CAS latency)

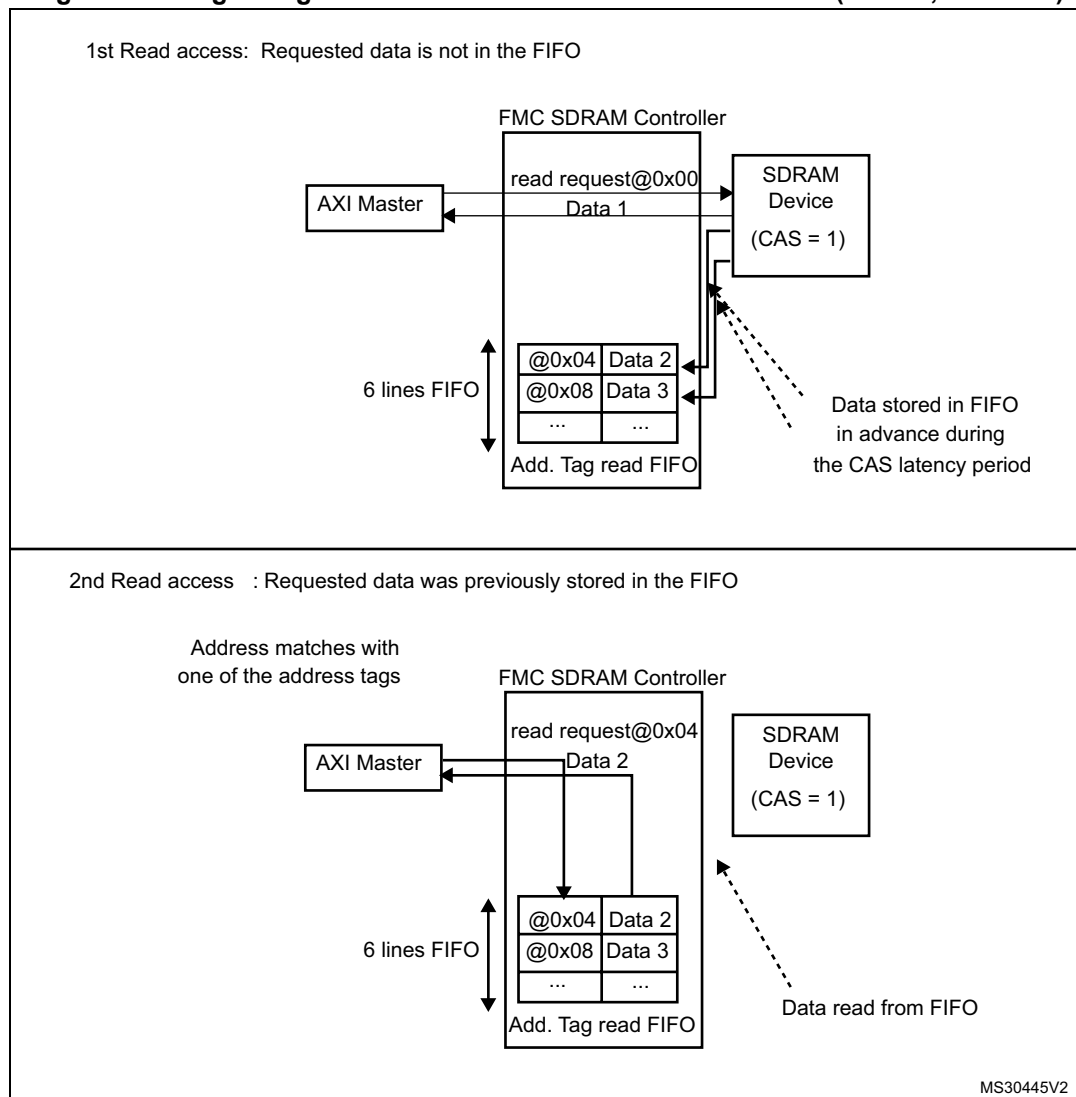

The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an burst read transaction, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

**Figure 110. Logic diagram of Read access with RBURST bit set (CAS=2, RPIPE=0)**

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to '1' in the FMC\_SDCR1 register.

The address management depends on the next AXI request:

- Next request is sequential (Burst access)  
In this case, the SDRAM controller increments the address.
- Next request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RBURST is reset, the read FIFO is not used.

### Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC\_SDTRx register.

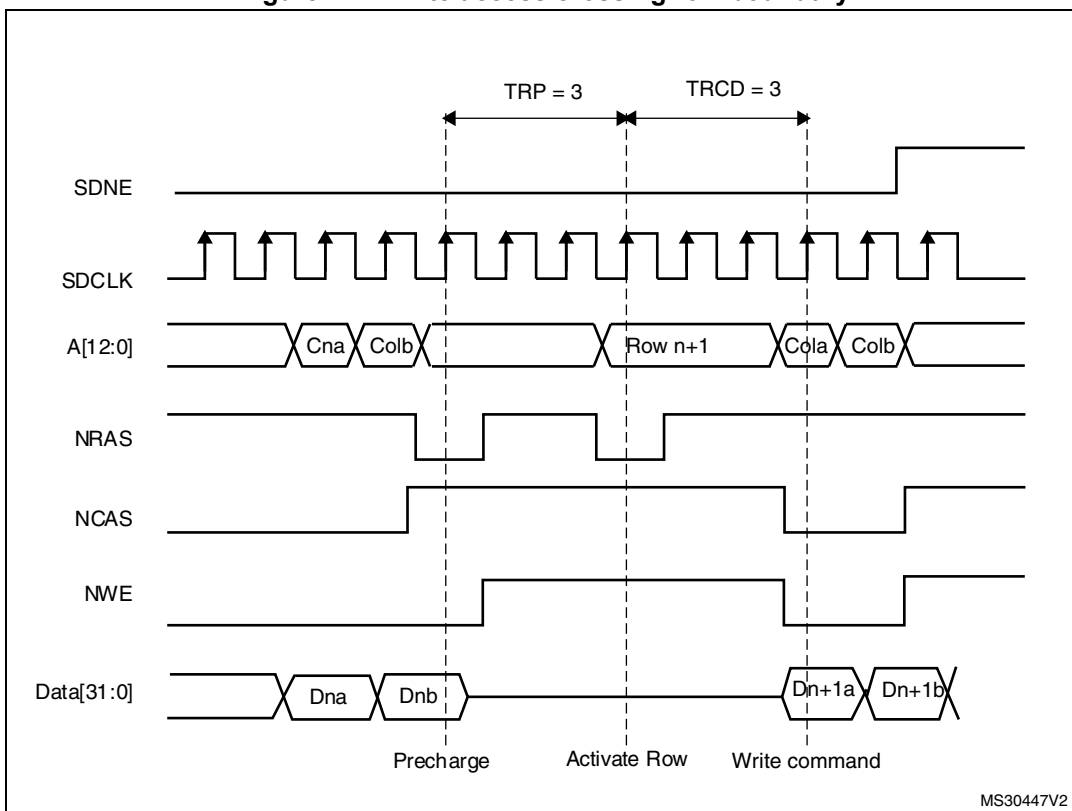

Refer to [Figure 108](#) and [Figure 109](#) for read and burst write access crossing a row boundary.

Figure 111. Read access crossing row boundary

MS30446V2

Figure 112. Write access crossing row boundary

MS30447V2

If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged. At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AXI slave error is generated.
- In case of 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, at boundary bank, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  - a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  - b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

### SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC\_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = '1').

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC\_SDCMR Command Mode register (Mode bits = '011'), a PALL command (Mode bits = '010') must be issued first.

## 22.9.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode  
The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode  
The auto-refresh cycles are performed by the SDRAM controller.

### Self-refresh mode

This mode is selected by setting the MODE bits to '101' and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.

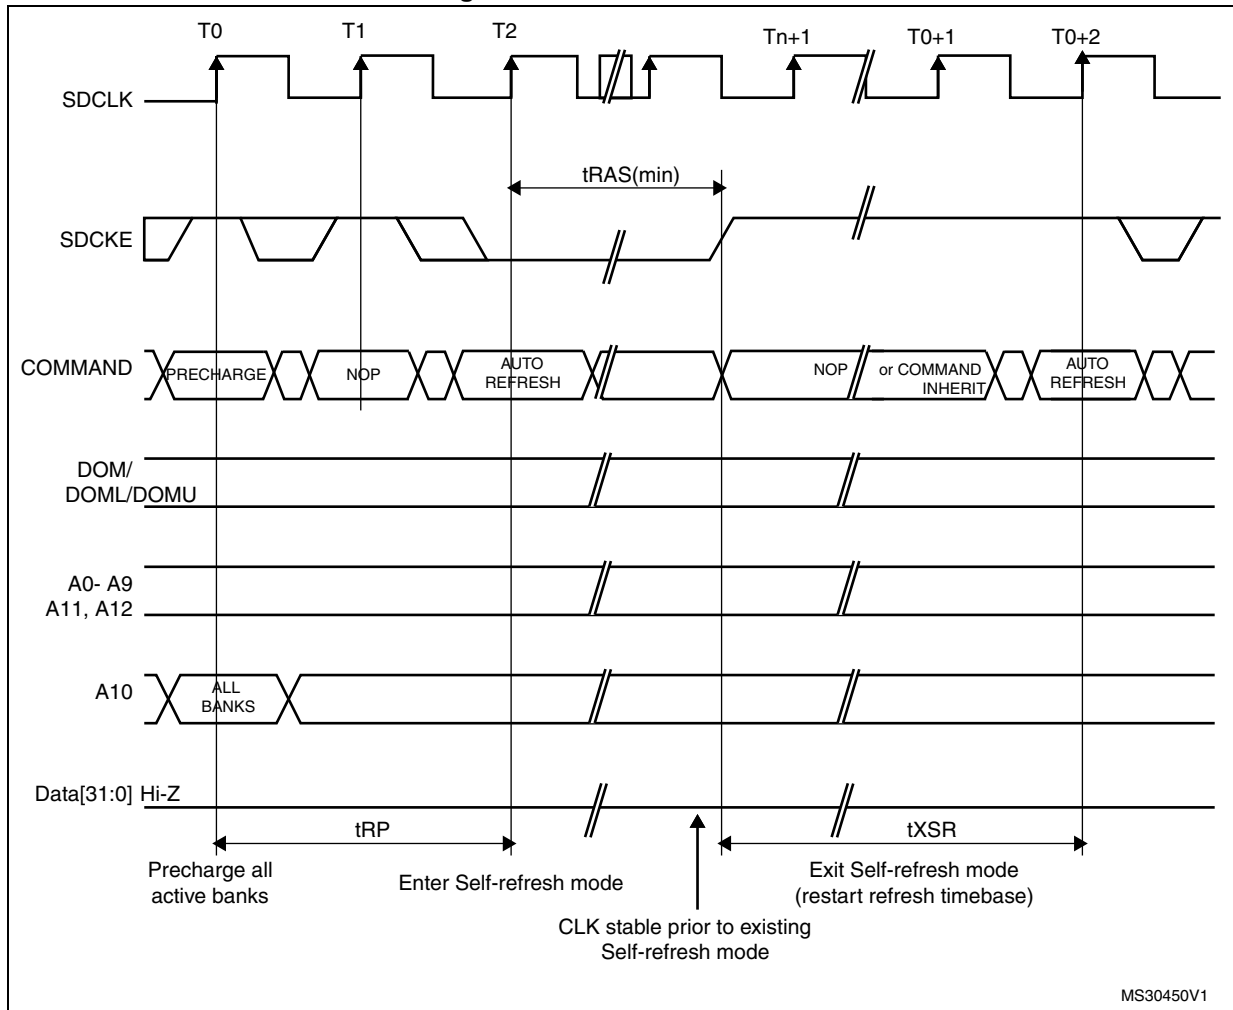

In Self-refresh mode, all SDRAM device inputs become don't care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC\_SDCMR register.

Figure 113. Self-refresh mode

**Power-down mode**

This mode is selected by setting the MODE bits to '110' and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register.

**Figure 114. Power-down mode**

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC\_SDCMR register.

## 22.9.5 SDRAM controller registers

### SDRAM Control registers 1,2 (FMC\_SDCR1,2)

Address offset:  $0x140 + 4 * (x - 1)$ ,  $x = 1,2$

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15
Res.	RPIPE[1:0]		RBURST	SDCLK[1:0]		WP	CAS[1:0]		NB	MWID[1:0]		NR[1:0]		NC5[1:0]		Res.
	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	

Bits 31:15 Reserved, must be kept at reset value

Bits 14:13 **RPIPE[1:0]**: Read pipe

These bits define the delay, in fmc\_ker\_ck clock cycles, for reading data after CAS latency.

- 00: No fmc\_ker\_ck clock cycle delay
- 01: One fmc\_ker\_ck clock cycle delay
- 10: Two fmc\_ker\_ck clock cycle delay
- 11: reserved.

*Note: The corresponding bits in the FMC\_SDCR2 register is read only.*

Bit 12 **RBURST**: Burst read

This bit enables burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.

- 0: single read requests are not managed as bursts
- 1: single read requests are always managed as bursts

*Note: The corresponding bit in the FMC\_SDCR2 register is read only.*

Bits 11:10 **SDCLK[1:0]**: SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.

- 00: SDCLK clock disabled
- 01: Reserved
- 10: SDCLK period = 2 x fmc\_ker\_ck periods
- 11: SDCLK period = 3 x fmc\_ker\_ck periods

*Note: The corresponding bits in the FMC\_SDCR2 register is read only.*

Bit 9 **WP**: Write protection

This bit enables write mode access to the SDRAM bank.

- 0: Write accesses allowed
- 1: Write accesses ignored

Bits 8:7 **CAS[1:0]**: CAS Latency

This bits sets the SDRAM CAS latency in number of memory clock cycles

00: reserved.

01: 1 cycle

10: 2 cycles

11: 3 cycles

Bit 6 **NB**: Number of internal banks

This bit sets the number of internal banks.

0: Two internal Banks

1: Four internal Banks

Bits 5:4 **MWID[1:0]**: Memory data bus width.

These bits define the memory device width.

00: 8 bits

01: 16 bits

10: 32 bits

11: reserved.

Bits 3:2 **NR[1:0]**: Number of row address bits

These bits define the number of bits of a row address.

00: 11 bit

01: 12 bits

10: 13 bits

11: reserved.

Bits 1:0 **NC[1:0]**: Number of column address bits

These bits define the number of bits of a column address.

00: 8 bits

01: 9 bits

10: 10 bits

11: 11 bits.

*Note:* Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

**SDRAM Timing registers 1,2 (FMC\_SDTR1,2)**

Address offset:  $0x148 + 4 * (x - 1)$ ,  $x = 1,2$

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TRCD				TRP				TWR			
				r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRC				TRAS				TXSR				TMRD			
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:28 Reserved, must be kept at reset value

Bits 27:24 **TRCD[3:0]**: Row to column delay

These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.

0000: 1 cycle.

0001: 2 cycles

....

1111: 16 cycles

Bits 23:20 **TRP[3:0]**: Row precharge delay

These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: The corresponding bits in the FMC\_SDTR2 register are don't care.*

Bits 19:16 **TWR[3:0]**: Recovery delay

These bits define the delay between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: TWR must be programmed to match the write recovery time ( $t_{WR}$ ) defined in the SDRAM datasheet, and to guarantee that:*

$$TWR \geq TRAS - TRCD \text{ and } TWR \geq TRC - TRCD - TRP$$

*Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR  $\geq$  2 cycles. TWR must be programmed to 0x1.*

*If two SDRAM devices are used, the FMC\_SDTR1 and FMC\_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.*

Bits 15:12 **TRC[3:0]**: Row cycle delay

These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.*

*Note: The corresponding bits in the FMC\_SDTR2 register are don't care.*

Bits 11:8 **TRAS[3:0]**: Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 7:4 **TXSR[3:0]**: Exit Self-refresh delay

These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.

- 0000: 1 cycle
- 0001: 2 cycles
- ....
- 1111: 16 cycles

*Note: If two SDRAM devices are used, the FMC\_SDTR1 and FMC\_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.*

Bits 3:0 **TMRD[3:0]**: Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.

- 0000: 1 cycle
- 0001: 2 cycles
- ....
- 1111: 16 cycles

*Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC\_SDTR1 register.*

*The TRP and TRC timings are only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.*

**SDRAM Command Mode register (FMC\_SDCMR)**

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command will be issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MRD						
									rW	rW	rW	rW	rW	rW	rW
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MRD							NRFS				CTB1	CTB2	MODE		
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 31:23 Reserved, must be kept at reset value

Bits 22:9 **MRD[13:0]**: Mode Register definition

This 14-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command. The MRD[13:0] bits are also used to program the extended mode register for mobile SDRAM.

Bits 8:5 **NRFS[3:0]**: Number of Auto-refresh

These bits define the number of consecutive Auto-refresh commands issued when MODE = '011'.

0000: 1 Auto-refresh cycle

0001: 2 Auto-refresh cycles

....

1110: 15 Auto-refresh cycles

1111: 16 Auto-refresh cycles

Bit 4 **CTB1**: Command Target Bank 1

This bit indicates whether the command will be issued to SDRAM Bank 1 or not.

0: Command not issued to SDRAM Bank 1

1: Command issued to SDRAM Bank 1

Bit 3 **CTB2**: Command Target Bank 2

This bit indicates whether the command will be issued to SDRAM Bank 2 or not.

0: Command not issued to SDRAM Bank 2

1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]**: Command mode

These bits define the command issued to the SDRAM device.

000: Normal Mode

001: Clock Configuration Enable

010: PALL ("All Bank Precharge") command

011: Auto-refresh command

100: Load Mode Register

101: Self-refresh command

110: Power-down command

111: Reserved

*Note: When a command is issued, at least one Command Target Bank bit ( CTB1 or CTB2) must be set otherwise the command will be ignored.*

*Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command will be ignored.*

*Note: If only one SDRAM bank is used and a command is issued with it's associated CTB bit set, the other CTB bit of the unused bank must be kept to 0.*

### SDRAM Refresh Timer register (FMC\_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}$$

$$\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20$$

**Example**

$$\text{Refresh rate} = 64 \text{ ms} / (8196 \text{ rows}) = 7.81 \mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81 \mu\text{s} \times 60 \text{ MHz} = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC\_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	REIE	COUNT													CRE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w

Bits 31: 15 Reserved, must be kept at reset value

Bit 14 **REIE**: RES Interrupt Enable  
 0: Interrupt is disabled  
 1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]**: Refresh Timer Count  
 This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 41 SDRAM clock cycles (0x29).  
 Refresh rate = (COUNT + 1) x SDRAM frequency clock  
 COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE**: Clear Refresh error flag  
 This bit is used to clear the Refresh Error Flag (RE) in the Status Register.  
 0: no effect  
 1: Refresh Error flag is cleared

*Note:* The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles .

**SDRAM Status register (FMC\_SDSR)**

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODES2		MODES1		RE
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value

Bits 4:3 **MODES2**: Status Mode for Bank 2

These bits define the Status Mode of SDRAM Bank 2.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bits 2:1 **MODES1**: Status Mode for Bank 1

These bits define the Status Mode of SDRAM Bank 1.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bit 0 **RE**: Refresh error flag

0: No refresh error has been detected

1: A refresh error has been detected

An interrupt is generated if REIE = 1 and RE = 1

## 22.10 FMC register map

The following table summarizes the FMC registers.

Table 181. FMC register map

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 23 Quad-SPI interface (QUADSPI)

### 23.1 Introduction

The QUADSPI is a specialized communication interface targeting single, dual or quad SPI Flash memories. It can operate in any of the three following modes:

- indirect mode: all the operations are performed using the QUADSPI registers
- status polling mode: the external Flash memory status register is periodically read and an interrupt can be generated in case of flag setting
- memory-mapped mode: the external Flash memory is mapped to the microcontroller address space and is seen by the system as if it was an internal memory

Both throughput and capacity can be increased two-fold using dual-flash mode, where two Quad-SPI Flash memories are accessed simultaneously.

### 23.2 QUADSPI main features

- Three functional modes: indirect, status-polling, and memory-mapped
- Dual-flash mode, where 8 bits can be sent/received simultaneously by accessing two Flash memories in parallel.
- SDR and DDR support
- Fully programmable opcode for both indirect and memory mapped mode
- Fully programmable frame format for both indirect and memory mapped mode
- Integrated FIFO for reception and transmission
- 8, 16, and 32-bit data accesses are allowed
- MDMA trigger generation for FIFO threshold and transfer complete
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error

### 23.3 QUADSPI functional description

#### 23.3.1 QUADSPI block diagram

Figure 115. QUADSPI block diagram when dual-flash mode is disabled

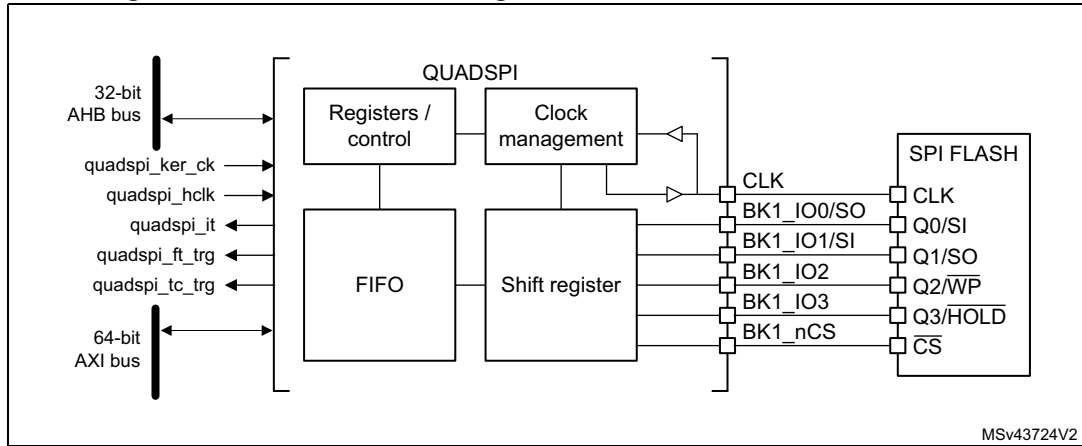

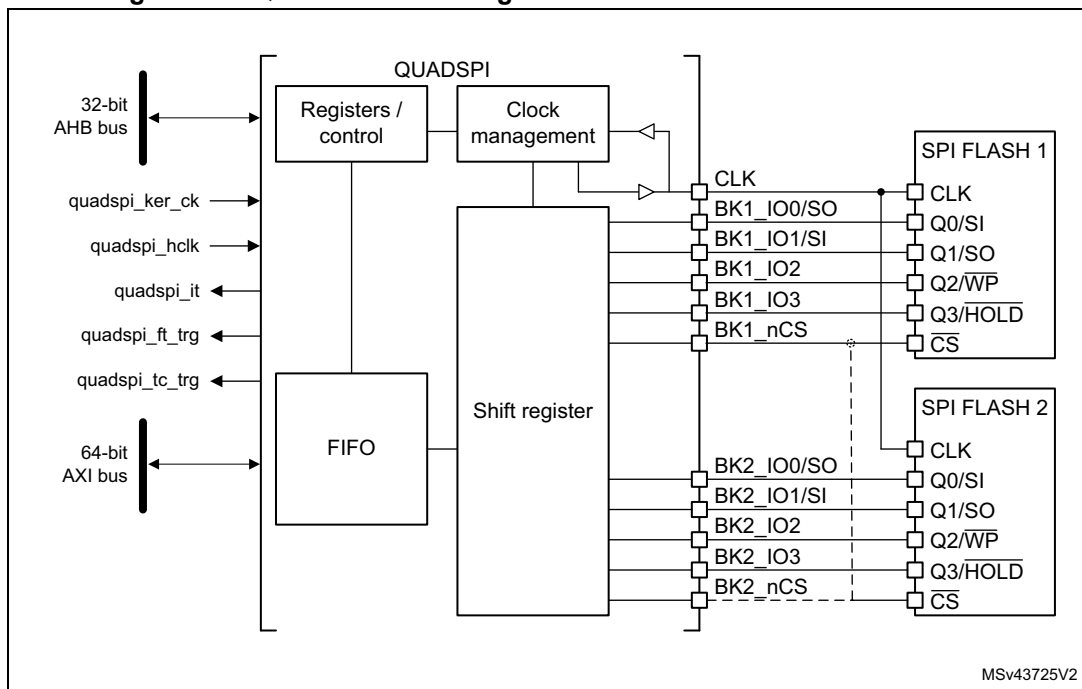

Figure 116. QUADSPI block diagram when dual-flash mode is enabled

### 23.3.2 QUADSPI pins and internal signals

*Table 182* lists the QUADSPI internal signals.

**Table 182. QUADSPI internal signals**

Signal name	Signal type	Description
quadspi_ker_ck	Digital input	QUADSPI kernel clock
quadspi_hclk	Digital input	QUADSPI register interface clock
quadspi_it	Digital output	QUADSPI global interrupt
quadspi_ft_trg	Digital output	QUADSPI FIFO threshold trigger for MDMA
quadspi_tc_trg	Digital output	QUADSPI transfer complete trigger for MDMA

*Table 183* lists the QUADSPI pins, six for interfacing with a single Flash memory, or 10 to 11 for interfacing with two Flash memories (FLASH 1 and FLASH 2) in dual-flash mode.

**Table 183. QUADSPI pins**

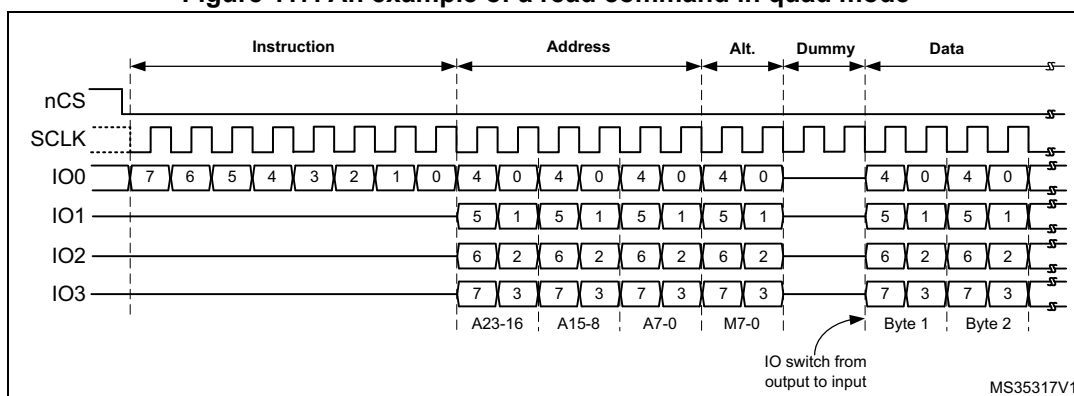

Signal name	Signal type	Description
CLK	Digital output	Clock to FLASH 1 and FLASH 2
BK1_IO0/SO	Digital input/output	Bidirectional IO in dual/quad modes or serial output in single mode, for FLASH 1
BK1_IO1/SI	Digital input/output	Bidirectional IO in dual/quad modes or serial input in single mode, for FLASH 1
BK1_IO2	Digital input/output	Bidirectional IO in quad mode, for FLASH 1
BK1_IO3	Digital input/output	Bidirectional IO in quad mode, for FLASH 1
BK2_IO0/SO	Digital input/output	Bidirectional IO in dual/quad modes or serial output in single mode, for FLASH 2
BK2_IO1/SI	Digital input/output	Bidirectional IO in dual/quad modes or serial input in single mode, for FLASH 2
BK2_IO2	Digital input/output	Bidirectional IO in quad mode, for FLASH 2
BK2_IO3	Digital input/output	Bidirectional IO in quad mode, for FLASH 2
BK1_nCS	Digital output	Chip select (active low) for FLASH 1. Can also be used for FLASH 2 if QUADSPI is always used in dual-flash mode.
BK2_nCS	Digital output	Chip select (active low) for FLASH 2. Can also be used for FLASH 1 if QUADSPI is always used in dual-flash mode.

### 23.3.3 QUADSPI Command sequence

The QUADSPI communicates with the Flash memory using commands. Each command can include 5 phases: instruction, address, alternate byte, dummy, data. Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phase must be present.

nCS falls before the start of each command and rises again after each command finishes.

Figure 117. An example of a read command in quad mode

### Instruction phase

During this phase, an 8-bit instruction, configured in INSTRUCTION field of QUADSPI\_CCR[7:0] register, is sent to the Flash memory, specifying the type of operation to be performed.

Though most Flash memories can receive instructions only one bit at a time from the IO0/SO signal (single SPI mode), the instruction phase can optionally send 2 bits at a time (over IO0/IO1 in dual SPI mode) or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the IMODE[1:0] field of QUADSPI\_CCR[9:8] register.

When IMODE = 00, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

### Address phase

In the address phase, 1-4 bytes are sent to the Flash memory to indicate the address of the operation. The number of address bytes to be sent is configured in the ADSIZE[1:0] field of QUADSPI\_CCR[13:12] register. In indirect and automatic-polling modes, the address bytes to be sent are specified in the ADDRESS[31:0] field of QUADSPI\_AR register, while in memory-mapped mode the address is given directly via the AXI (from the Cortex® or from a DMA).

The address phase can send 1 bit at a time (over SO in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the ADMODE[1:0] field of QUADSPI\_CCR[11:10] register.

When ADMODE = 00, the address phase is skipped, and the command sequence proceeds directly to the next phase, if any.

### Alternate-bytes phase

In the alternate-bytes phase, 1-4 bytes are sent to the Flash memory, generally to control the mode of operation. The number of alternate bytes to be sent is configured in the ABSIZE[1:0] field of QUADSPI\_CCR[17:16] register. The bytes to be sent are specified in the QUADSPI\_ABR register.

The alternate-bytes phase can send 1 bit at a time (over SO in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the ABMODE[1:0] field of QUADSPI\_CCR[15:14] register.

When `ABMODE = 00`, the alternate-bytes phase is skipped, and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when dual-mode is used and only two cycles are used for the alternate bytes. In this case, firmware can use quad-mode (`ABMODE = 11`) and send a byte with bits 7 and 3 of `ALTERNATE` set to '1' (keeping the `IO3` line high), and bits 6 and 2 set to '0' (keeping the `IO2` line low). In this case the upper two bits of the nibble to be sent are placed in bits 4:3 of `ALTERNATE` while the lower two bits are placed in bits 1 and 0. For example, if the nibble 2 (0010) is to be sent over `IO0/IO1`, then `ALTERNATE` should be set to 0x8A (1000\_1010).

### Dummy-cycles phase

In the dummy-cycles phase, 1-31 cycles are given without any data being sent or received, in order to allow the Flash memory the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in the `DCYC[4:0]` field of `QUADSPI_CCR[22:18]` register. In both SDR and DDR modes, the duration is specified as a number of full `CLK` cycles.

When `DCYC` is zero, the dummy-cycles phase is skipped, and the command sequence proceeds directly to the data phase, if present.

The operating mode of the dummy-cycles phase is determined by `DMODE`.

In order to assure enough "turn-around" time for changing the data signals from output mode to input mode, there must be at least one dummy cycle when using dual or quad mode to receive data from the Flash memory.

### Data phase

During the data phase, any number of bytes can be sent to, or received from the Flash memory.

In indirect and automatic-polling modes, the number of bytes to be sent/received is specified in the `QUADSPI_DLR` register.

In indirect write mode the data to be sent to the Flash memory must be written to the `QUADSPI_DR` register, while in indirect read mode the data received from the Flash memory is obtained by reading from the `QUADSPI_DR` register.

In memory-mapped mode, the data which is read is sent back directly over the `AXI` to the Cortex or to a DMA.

The data phase can send/receive 1 bit at a time (over `SO/SI` in single SPI mode), 2 bits at a time (over `IO0/IO1` in dual SPI mode), or 4 bits at a time (over `IO0/IO1/IO2/IO3` in quad SPI mode). This can be configured using the `ABMODE[1:0]` field of `QUADSPI_CCR[15:14]` register.

When `DMODE = 00`, the data phase is skipped, and the command sequence finishes immediately by raising `nCS`. This configuration must only be used in only indirect write mode.

### 23.3.4 QUADSPI signal interface protocol modes

#### Single SPI mode

Legacy SPI mode allows just a single bit to be sent/received serially. In this mode, data is sent to the Flash memory over the SO signal (whose I/O shared with IO0). Data received from the Flash memory arrives via SI (whose I/O shared with IO1).

The different phases can each be configured separately to use this single bit mode by setting the IMODE/ADMODE/ABMODE/DMODE fields (in QUADSPI\_CCR) to 01.

In each phase which is configured in single mode:

- IO0 (SO) is in output mode
- IO1 (SI) is in input mode (high impedance)
- IO2 is in output mode and forced to '0' (to deactivate the "write protect" function)
- IO3 is in output mode and forced to '1' (to deactivate the "hold" function)

This is the case even for the dummy phase if DMODE = 01.

#### Dual SPI mode

In dual SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI\_CCR register to 10.

In each phase which is configured in dual mode:

- IO0/IO1 are at high-impedance (input) during the data phase for read operations, and outputs in all other cases
- IO2 is in output mode and forced to '0'
- IO3 is in output mode and forced to '1'

In the dummy phase when DMODE = 01, IO0/IO1 are always high-impedance.

#### Quad SPI mode

In quad SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use quad SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI\_CCR register to 11.

In each phase which is configured in quad mode, IO0/IO1/IO2/IO3 are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE = 11, IO0/IO1/IO2/IO3 are all high-impedance.

IO2 and IO3 are used only in Quad SPI mode. If none of the phases are configured to use Quad SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while QUADSPI is active.

#### SDR mode

By default, the DDRM bit (QUADSPI\_CCR[31]) is 0 and the QUADSPI operates in single data rate (SDR) mode.

In SDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the QUADSPI assumes that the Flash memories also send the data using CLK's falling edge. By default (when SSHIFT = 0), the signals are sampled using the following (rising) edge of CLK.

**DDR mode**

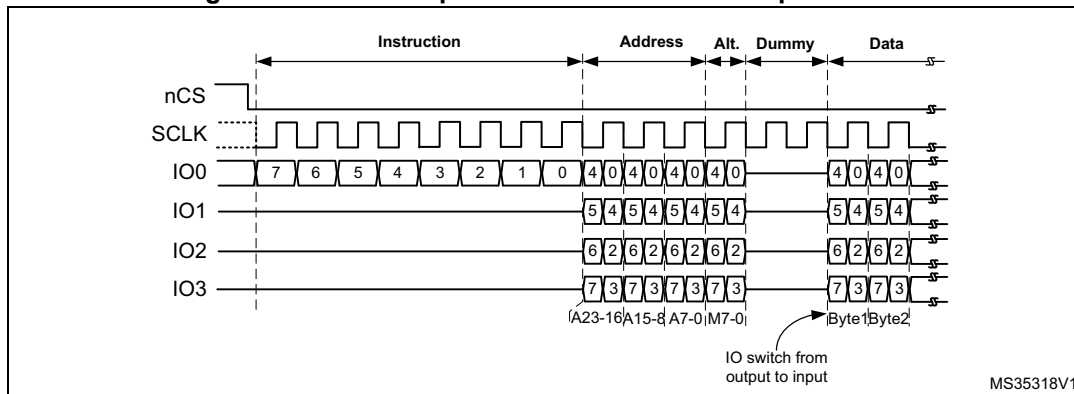

When the DDRM bit (QUADSPI\_CCR[31]) is set to 1, the QUADSPI operates in double data rate (DDR) mode.

In DDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals in the address/alternate-byte/data phases, a bit is sent on each of the falling and rising edges of CLK.

The instruction phase is not affected by DDRM. The instruction is always sent using CLK's falling edge.

When receiving data in DDR mode, the QUADSPI assumes that the Flash memories also send the data using both rising and falling CLK edges. When DDRM = 1, firmware must clear SSHIFT bit (bit 4 of QUADSPI\_CR). Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

**Figure 118. An example of a DDR command in quad mode**

**Dual-flash mode**

When the DFM bit (bit 6 of QUADSPI\_CR) is 1, the QUADSPI is in dual-flash mode, where two external quad SPI Flash memories (FLASH 1 and FLASH 2) are used in order to send/receive 8 bits (or 16 bits in DDR mode) every cycle, effectively doubling the throughput as well as the capacity.

Each of the Flash memories use the same CLK and optionally the same nCS signals, but each have separate IO0, IO1, IO2, and IO3 signals.

Dual-flash mode can be used in conjunction with single-bit, dual-bit, and quad-bit modes, as well as with either SDR or DDR mode.

The Flash memory size, as specified in FSIZE[4:0] (QUADSPI\_DCR[20:16]), should reflect the total Flash memory capacity, which is double the size of one individual component.

If address X is even, then the byte which the QUADSPI gives for address X is the byte at the address X/2 of FLASH 1, and the byte which the QUADSPI gives for address X+1 is the byte at the address X/2 of FLASH 2. In other words, bytes at even addresses are all stored in FLASH 1 and bytes at odd addresses are all stored in FLASH 2.

When reading the Flash memories status registers in dual-flash mode, twice as many bytes should be read compared to doing the same read in single-flash mode. This means that if each Flash memory gives 8 valid bits after the instruction for fetching the status register, then the QUADSPI must be configured with a data length of 2 bytes (16 bits), and the QUADSPI will receive one byte from each Flash memory. If each Flash memory gives a status of 16 bits, then the QUADSPI must be configured to read 4 bytes to get all the status bits of both Flash memories in dual-flash mode. The least-significant byte of the result (in the data register) is the least-significant byte of FLASH 1 status register, while the next byte is the least-significant byte of FLASH 2 status register. Then, the third byte of the data register is FLASH 1 second byte, while the fourth byte is FLASH 2 second byte (in the case that the Flash memories have 16-bit status registers).

An even number of bytes must always be accessed in dual-flash mode. For this reason, bit 0 of the data length field (QUADSPI\_DLR[0]) is stuck at 1 when DRM = 1.

In dual-flash mode, the behavior of FLASH 1 interface signals are basically the same as in normal mode. FLASH 2 interface signals have exactly the same waveforms as FLASH 1 during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each Flash memory always receives the same instruction and the same address. Then, during the data phase, the BK1\_IOx and BK2\_IOx buses are both transferring data in parallel, but the data that are sent to (or received from) FLASH 1 are distinct from those of FLASH 2.

### 23.3.5 QUADSPI indirect mode

When in indirect mode, commands are started by writing to QUADSPI registers and data is transferred by writing or reading the data register, in the same way as for other communication peripherals.

When FMODE = 00 (QUADSPI\_CCR[27:26]), the QUADSPI is in indirect write mode, where bytes are sent to the Flash memory during the data phase. Data are provided by writing to the data register (QUADSPI\_DR).

When FMODE = 01, the QUADSPI is in indirect read mode, where bytes are received from the Flash memory during the data phase. Data are recovered by reading QUADSPI\_DR.

The number of bytes to be read/written is specified in the data length register (QUADSPI\_DLR). If QUADSPI\_DLR = 0xFFFF\_FFFF (all 1's), then the data length is considered undefined and the QUADSPI simply continues to transfer data until the end of Flash memory (as defined by FSIZE) is reached. If no bytes are to be transferred, DMODE (QUADSPI\_CCR[25:24]) should be set to 00.

If QUADSPI\_DLR = 0xFFFF\_FFFF and FSIZE = 0x1F (max value indicating a 4GB Flash memory), then in this special case the transfers continue indefinitely, stopping only after an abort request or after the QUADSPI is disabled. After the last memory address is read (at address 0xFFFF\_FFFF), reading continues with address = 0x0000\_0000.

When the programmed number of bytes to be transmitted or received is reached, TCF is set and an interrupt is generated if TCIE = 1. In the case of undefined number of data, the TCF is set when the limit of the external SPI memory is reached according to the Flash memory size defined in the QUADSPI\_CR.

### Triggering the start of a command

Essentially, a command starts as soon as firmware gives the last information that is necessary for this command. Depending on the QUADSPI configuration, there are three different ways to trigger the start of a command in indirect mode. The commands starts immediately after:

1. a write is performed to INSTRUCTION[7:0] (QUADSPI\_CCR), if no address is necessary (when ADMODE = 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
2. a write is performed to ADDRESS[31:0] (QUADSPI\_AR), if an address is necessary (when ADMODE != 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
3. a write is performed to DATA[31:0] (QUADSPI\_DR), if an address is necessary (when ADMODE != 00) and if data needs to be provided by the firmware (when FMODE = 00 and DMODE != 00)

Writes to the alternate byte register (QUADSPI\_ABR) never trigger the communication start. If alternate bytes are required, they must be programmed before.

As soon as a command is started, the BUSY bit (bit 5 of QUADSPI\_SR) is automatically set.

### FIFO and data management

In indirect mode, data go through a 32-byte FIFO which is internal to the QUADSPI. FLEVEL[5:0] (QUADSPI\_SR[13:8]) indicates how many bytes are currently being held in the FIFO.

In indirect write mode (FMODE = 00), firmware adds data to the FIFO when it writes QUADSPI\_DR. Word writes add 4 bytes to the FIFO, halfword writes add 2 bytes, and byte writes add only 1 byte. If firmware adds too many bytes to the FIFO (more than is indicated by DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

Byte/halfword accesses to QUADSPI\_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES[3:0] is used to define a FIFO threshold. When the threshold is reached, the FTF (FIFO threshold flag) is set. In indirect read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there are data in the FIFO after the last byte is read from the Flash memory, regardless of the FTHRES setting. In indirect write mode, FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when FTF is set. FTF is cleared by HW as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect read mode when the FIFO becomes full, the QUADSPI temporarily stops reading bytes from the Flash memory to avoid an overrun. Please note that the reading of the Flash memory does not restart until 4 bytes become vacant in the FIFO (when FLEVEL ≤ 11). Thus, when FTHRES ≥ 13, the application must take care to read enough bytes to assure that the QUADSPI starts retrieving data from the Flash memory again. Otherwise, the FTF flag stays at '0' as long as 11 < FLEVEL < FTHRES.

### 23.3.6 QUADSPI status flag polling mode

In automatic-polling mode, the QUADSPI periodically starts a command to read a defined number of status bytes (up to 4). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The accesses to the Flash memory begin in the same way as in indirect read mode: if no address is required (AMODE = 00), accesses begin as soon as the QUADSPI\_CCR is written. Otherwise, if an address is required, the first access begins when QUADSPI\_AR is written. BUSY goes high at this point and stays high even between the periodic accesses.

The contents of MASK[31:0] (QUADSPI\_PSMAR) are used to mask the data from the Flash memory in automatic-polling mode. If the MASK[n] = 0, then bit n of the result is masked and not considered. If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] (QUADSPI\_PSMAR), then there is a match for bit n.

If the polling match mode bit (PMM, bit 23 of QUADSPI\_CR) is 0, then “AND” match mode is activated. This means status match flag (SMF) is set only when there is a match on all of the unmasked bits.

If PMM = 1, then “OR” match mode is activated. This means SMF is set if there is a match on any of the unmasked bits.

An interrupt is called when SMF is set if SMIE = 1.

If the automatic-polling-mode-stop (APMS) bit is set, operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at '1' and the periodic accesses continue until there is an abort or the QUADSPI is disabled (EN = 0).

The data register (QUADSPI\_DR) contains the latest received status bytes (the FIFO is deactivated). The content of the data register is not affected by the masking used in the matching logic. The FTF status bit is set as soon as a new reading of the status is complete, and FTF is cleared as soon as the data is read.

### 23.3.7 QUADSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

It is forbidden to access QUADSPI Flash bank area before having properly configured and enabled the QUADSPI peripheral.

No more than 256MB can be addressed even if the Flash memory capacity is larger.

If an access is made to an address outside of the range defined by FSIZE but still within the 256MB range, then a bus error is given. The effect of this error depends on the bus master that attempted the access:

- If it is the Cortex<sup>®</sup> CPU, bus fault exception is generated when enabled (or a hard fault exception when bus fault is disabled)
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, halfword, and word access types are all supported.

Support for execute in place (XIP) operation is implemented, where the QUADSPI anticipates the next microcontroller access and loads in advance the byte at the following address. If the subsequent access is indeed made at a continuous address, the access will be completed faster since the value is already prefetched.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with nCS maintained low, even if no access to the Flash memory occurs for a long time. Since Flash memories tend to consume more when nCS is held low, the application might want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI\_CR) so that nCS is released after a period of TIMEOUT[15:0] (QUADSPI\_LPTR) cycles have elapsed without any access since when the FIFO becomes full with prefetch data.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is a timeout, there is an abort, or the peripheral is disabled.

### 23.3.8 QUADSPI Free running clock mode

When configured in Free running clock mode, the QUADSPI peripheral continuously outputs the clock for test and calibration purposes.

Free running clock mode is entered as soon as the Free running clock mode bit (FRCM) is set in the QUADSPI communication configuration register (QUADSPI\_CCR). It is exited by setting the ABORT bit of the QUADSPI control register (QUADSPI\_CR).

When the QUADSPI operates in Free running clock mode:

- the clock is running continuously,
- nCS stays High (external device deselected),
- data lines are released (High-Z),
- the BUSY flag of the QUADSPI status register (QUADSPI\_SR) is set.

### 23.3.9 QUADSPI Flash memory configuration

The device configuration register (QUADSPI\_DCR) can be used to specify the characteristics of the external SPI Flash memory.

The FSIZE[4:0] field defines the size of external memory using the following formula:

$$\text{Number of bytes in Flash memory} = 2^{[\text{FSIZE}+1]}$$

FSIZE+1 is effectively the number of address bits required to address the Flash memory. The Flash memory capacity can be up to 4GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256MB.

If DFM = 1, FSIZE indicates the total capacity of the two Flash memories together.

When the QUADSPI executes two commands, one immediately after the other, it raises the chip select signal (nCS) high between the two commands for only one CLK cycle by default. If the Flash memory requires more time between commands, the chip select high time (CSHT) field can be used to specify the minimum number of CLK cycles (up to 8) that nCS must remain high.

The clock mode (CKMODE) bit indicates the CLK signal logic level in between commands (when nCS = 1).

### 23.3.10 QUADSPI delayed data sampling

By default, the QUADSPI samples the data driven by the Flash memory one half of a CLK cycle after the Flash memory drives the signal.

In case of external signal delays, it may be beneficial to sample the data later. Using the SSHIFT bit (bit 4 of QUADSPI\_CR), the sampling of the data can be shifted by half of a CLK cycle.

Clock shifting is not supported in DDR mode: the SSHIFT bit must be clear when DDRM bit is set.

### 23.3.11 QUADSPI configuration

The QUADSPI configuration is done in two phases:

- QUADSPI IP configuration
- QUADSPI Flash memory configuration

Once configured and enabled, the QUADSPI can be used in one of its three operating modes: indirect mode, status-polling mode, or memory-mapped mode.

QUADSPI IP configuration

The QUADSPI IP is configured using the QUADSPI\_CR. The user shall configure the clock prescaler division factor and the sample shifting settings for the incoming data.

DDR mode can be set through the DDRM bit. Once enabled, the address and the alternate bytes are sent on both clock edges and the data are sent/received on both clock edges. Regardless of the DDRM bit setting, instructions are always sent in SDR mode.

FIFO level for either MDMA trigger generation or interrupt generation is programmed in the FTHRES bits.

If timeout counter is needed, the TCEN bit can be set and the timeout value programmed in the QUADSPI\_LPTR register.

Dual-flash mode can be activated by setting DFM to 1.

#### QUADSPI Flash memory configuration

The parameters related to the targeted external Flash memory are configured through the QUADSPI\_DCR register. The user shall program the Flash memory size in the FSIZE bits, the Chip Select minimum high time in the CSHT bits, and the functional mode (Mode 0 or Mode 3) in the MODE bit.

### 23.3.12 QUADSPI usage

The operating mode is selected using FMODE[1:0] (QUADSPI\_CCR[27:26]).

#### Indirect mode procedure

When FMODE is programmed to 00, indirect write mode is selected and data can be sent to the Flash memory. With FMODE = 01, indirect read mode is selected where data can be read from the Flash memory.

When the QUADSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in the QUADSPI\_DLR.
2. Specify the frame format, mode and instruction code in the QUADSPI\_CCR.
3. Specify optional alternate byte to be sent right after the address phase in the QUADSPI\_ABR.
4. Specify the operating mode in the QUADSPI\_CR.
5. Specify the targeted address in the QUADSPI\_AR.
6. Read/Write the data from/to the FIFO through the QUADSPI\_DR.

When writing the control register (QUADSPI\_CR) the user specifies the following settings:

- The enable bit (EN) set to '1'
- Timeout counter enable bit (TCEN)
- Sample shift setting (SSHIFT)
- FIFO threshold level (FTRHES) to indicate when the FTF flag should be set
- Interrupt enables
- Automatic polling mode parameters: match mode and stop mode (valid when FMODE = 11)
- Clock prescaler

When writing the communication configuration register (QUADSPI\_CCR) the user specifies the following parameters:

- The instruction byte through the INSTRUCTION bits
- The way the instruction has to be sent through the IMODE bits (1/2/4 lines)
- The way the address has to be sent through the ADMODE bits (None/1/2/4 lines)
- The address size (8/16/24/32-bit) through the ADSIZE bits
- The way the alternate bytes have to be sent through the ABMODE (None/1/2/4 lines)
- The alternate bytes number (1/2/3/4) through the ABSIZE bits
- The presence or not of dummy bytes through the DBMODE bit
- The number of dummy bytes through the DCYC bits
- The way the data have to be sent/received (None/1/2/4 lines) through the DMODE bits

If neither the address register (QUADSPI\_AR) nor the data register (QUADSPI\_DR) need to be updated for a particular command, then the command sequence starts as soon as QUADSPI\_CCR is written. This is the case when both ADMODE and DMODE are 00, or if just ADMODE = 00 when in indirect read mode (FMODE = 01).

When an address is required (ADMODE is not 00) and the data register does not need to be written (when FMODE = 01 or DMODE = 00), the command sequence starts as soon as the address is updated with a write to QUADSPI\_AR.

In case of data transmission (FMODE = 00 and DMODE! = 00), the communication start is triggered by a write in the FIFO through QUADSPI\_DR.

### Status flag polling mode

The status flag polling mode is enabled setting the FMODE field (QUADSPI\_CCR[27:26]) to 10. In this mode, the programmed frame will be sent and the data retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in QUADSPI\_DLR, it will be ignored and only 4 bytes will be read.

The periodicity is specified in the QUADSPI\_PISR register.

Once the status data has been retrieved, it can internally be processed in order to:

- set the status match flag and generate an interrupt if enabled
- stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in the QUADSPI\_PSMKR and ORed or ANDed with the value stored in the QUADSPI\_PSMAR.

In case of match, the status match flag is set and an interrupt is generated if enabled, and the QUADSPI can be automatically stopped if the AMPS bit is set.

In any case, the latest retrieved value is available in the QUADSPI\_DR.

### Memory-mapped mode

In memory-mapped mode, the external Flash memory is seen as internal memory but with some latency during accesses. Only read operations are allowed to the external Flash memory in this mode.

Memory-mapped mode is entered by setting the FMODE to 11 in the QUADSPI\_CCR register.

The programmed instruction and frame is sent when a master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate linear reads. Any access to QUADSPI\_DR in this mode returns zero.

The data length register (QUADSPI\_DLR) has no meaning in memory-mapped mode.

### 23.3.13 Sending the instruction only once

Some Flash memories (e.g. Winbound) might provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. One can take advantage of such a feature using the SIOO bit (QUADSPI\_CCR[28]).

SIOO is valid for all functional modes (indirect, automatic polling, and memory-mapped). If the SIOO bit is set, the instruction is sent only for the first command following a write to QUADSPI\_CCR. Subsequent command sequences skip the instruction phase, until there is a write to QUADSPI\_CCR.

SIOO has no effect when IMODE = 00 (no instruction).

### 23.3.14 QUADSPI error management

An error can be generated in the following case:

- In indirect mode or status flag polling mode when a wrong address has been programmed in the QUADSPI\_AR (according to the Flash memory size defined by FSIZE[4:0] in the QUADSPI\_DCR): this will set the TEF and an interrupt is generated if enabled.
- Also in indirect mode, if the address plus the data length exceeds the Flash memory size, TEF will be set as soon as the access is triggered.
- In memory-mapped mode, when an out of range access is done by a master or when the QUADSPI is disabled: this will generate a bus error as a response to the faulty bus master request.
- When a master is accessing the memory mapped space while the memory mapped mode is disabled: this will generate a bus error as a response to the faulty bus master request.

### 23.3.15 QUADSPI busy bit and abort functionality

Once the QUADSPI starts an operation with the Flash memory, the BUSY bit is automatically set in the QUADSPI\_SR.

In indirect mode, the BUSY bit is reset once the QUADSPI has completed the requested command sequence and the FIFO is empty.

In automatic-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1, or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on a timeout event or on an abort.

Any operation can be aborted by setting the ABORT bit in the QUADSPI\_CR. Once the abort is completed, the BUSY bit and the ABORT bit are automatically reset, and the FIFO is flushed.

*Note:* Some Flash memories might misbehave if a write operation to a status registers is aborted.

### 23.3.16 nCS behavior

By default, nCS is high, deselecting the external Flash memory. nCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 ("mode0", where CLK stays low when no operation is in progress) nCS falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final rising CLK edge, as shown in [Figure 119](#).

**Figure 119. nCS when CKMODE = 0 (T = CLK period)**

When CKMODE=1 (“mode3”, where CLK goes high when no operation is in progress) and DDRM=0 (SDR mode), nCS still falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final rising CLK edge, as shown in [Figure 120](#).

**Figure 120. nCS when CKMODE = 1 in SDR mode (T = CLK period)**

When CKMODE = 1 (“mode3”) and DDRM = 1 (DDR mode), nCS falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final active rising CLK edge, as shown in [Figure 121](#). Because DDR operations must finish with a falling edge, CLK is low when nCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 121. nCS when CKMODE = 1 in DDR mode (T = CLK period)**

When the FIFO stays full in a read operation or if the FIFO stays empty in a write operation, the operation stalls and CLK stays low until firmware services the FIFO. If an abort occurs when an operation is stalled, nCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later, as shown in [Figure 122](#).

**Figure 122. nCS when CKMODE = 1 with an abort (T = CLK period)**

When not in dual-flash mode (DFM = 0), only FLASH 1 is accessed and thus the BK2\_nCS stays high. In dual-flash mode, BK2\_nCS behaves exactly the same as BK1\_nCS. Thus, if there is a FLASH 2 and if the application always stays in dual-flash mode, then FLASH 2 may use BK1\_nCS and the pin outputting BK2\_nCS can be used for other functions.

## 23.4 QUADSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**Table 184. QUADSPI interrupt requests**

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

## 23.5 QUADSPI registers

### 23.5.1 QUADSPI control register (QUADSPI\_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRESCALER								PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES					FSEL	DFM	Res.	SSHIFT	TCEN	Res.	ABORT	EN
			r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w	r/w		r/w	w1s

Bits 31: 24 **PRESCALER[7:0]**: Clock prescaler

This field defines the scaler factor for generating CLK based on the quadspi\_ker\_ck clock (value+1).

0:  $F_{CLK} = F_{quadspi\_ker\_ck}$ , quadspi\_ker\_ck clock used directly as QUADSPI CLK (prescaler bypassed)

1:  $F_{CLK} = F_{quadspi\_ker\_ck}/2$

2:  $F_{CLK} = F_{quadspi\_ker\_ck}/3$

...

255:  $F_{CLK} = F_{quadspi\_ker\_ck}/256$

For odd clock division factors, CLK's duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

This field can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode

This bit indicates which method should be used for determining a "match" during automatic polling mode.

0: AND match mode. SMF is set if all the unmasked bits received from the Flash memory match the corresponding bits in the match register.

1: OR match mode. SMF is set if any one of the unmasked bits received from the Flash memory matches its corresponding bit in the match register.

This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic poll mode stop

This bit determines if automatic polling is stopped after a match.

0: Automatic polling mode is stopped only by abort or by disabling the QUADSPI.

1: Automatic polling mode stops as soon as there is a match.

This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: TimeOut interrupt enable

This bit enables the TimeOut interrupt.

0: Interrupt disable

1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable

This bit enables the status match interrupt.

0: Interrupt disable

1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable

This bit enables the FIFO threshold interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable

This bit enables the transfer complete interrupt.

0: Interrupt disabled

1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable

This bit enables the transfer error interrupt.

0: Interrupt disable

1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]** FIFO threshold level

Defines, in indirect mode, the threshold number of bytes in the FIFO that will cause the FIFO threshold flag (FTF, QUADSPI\_SR[2]) to be set.

In indirect write mode (FMODE = 00):

0: FTF is set if there are 1 or more free bytes available to be written to in the FIFO

1: FTF is set if there are 2 or more free bytes available to be written to in the FIFO

...

31: FTF is set if there are 32 free bytes available to be written to in the FIFO

In indirect read mode (FMODE = 01):

0: FTF is set if there are 1 or more valid bytes that can be read from the FIFO

1: FTF is set if there are 2 or more valid bytes that can be read from the FIFO

...

31: FTF is set if there are 32 valid bytes that can be read from the FIFO

Bit 7 **FSEL**: Flash memory selection

This bit selects the Flash memory to be addressed in single flash mode (when DFM = 0).

0: FLASH 1 selected

1: FLASH 2 selected

This bit can be modified only when BUSY = 0.

This bit is ignored when DFM = 1.

Bit 6 **DFM**: Dual-flash mode

This bit activates dual-flash mode, where two external Flash memories are used simultaneously to double throughput and capacity.

0: Dual-flash mode disabled

1: Dual-flash mode enabled

This bit can be modified only when BUSY = 0.

Bit 5 Reserved, must be kept at reset value.

**Bit 4 SSHIFT:** Sample shift

By default, the QUADSPI samples data 1/2 of a CLK cycle after the data is driven by the Flash memory. This bit allows the data is to be sampled later in order to account for external signal delays.

0: No shift

1: 1/2 cycle shift

Firmware must assure that SSHIFT = 0 when in DDR mode (when DDRM = 1).

This field can be modified only when BUSY = 0.

**Bit 3 TCEN:** Timeout counter enable

This bit is valid only when memory-mapped mode (FMODE = 11) is selected. Activating this bit causes the chip select (nCS) to be released (and thus reduces consumption) if there has not been an access after a certain amount of time, where this time is defined by TIMEOUT[15:0] (QUADSPI\_LPTR).

Enable the timeout counter.

By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with nCS maintained low, even if no access to the Flash memory occurs for a long time. Since Flash memories tend to consume more when nCS is held low, the application might want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI\_CR) so that nCS is released after a period of TIMEOUT[15:0] (QUADSPI\_LPTR) cycles have elapsed without an access since when the FIFO becomes full with prefetch data.

0: Timeout counter is disabled, and thus the chip select (nCS) remains active indefinitely after an access in memory-mapped mode.

1: Timeout counter is enabled, and thus the chip select is released in memory-mapped mode after TIMEOUT[15:0] cycles of Flash memory inactivity.

This bit can be modified only when BUSY = 0.

**Bit 2** Reserved**Bit 1 ABORT:** Abort request

This bit aborts the on-going command sequence. It is automatically reset once the abort is complete.

This bit stops the current transfer.

In polling mode or memory-mapped mode, this bit also reset the APM bit or the DM bit.

0: No abort requested

1: Abort requested

**Bit 0 EN:** Enable

Enable the QUADSPI.

0: QUADSPI is disabled

1: QUADSPI is enabled

### 23.5.2 QUADSPI device configuration register (QUADSPI\_DCR)

Address offset: 0x0004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FSIZE				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CSHT			Res.	Res.	Res.	Res.	Res.	Res.	Res.	CK-MODE
					rw	rw	rw								rw

Bits 31: 21 Reserved, must be kept at reset value.

Bits 20: 16 **FSIZE[4:0]**: Flash memory size

This field defines the size of external memory using the following formula:  
 Number of bytes in Flash memory =  $2^{[FSIZE+1]}$

FSIZE+1 is effectively the number of address bits required to address the Flash memory. The Flash memory capacity can be up to 4GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256MB.

If DFM = 1, FSIZE indicates the total capacity of the two Flash memories together.  
 This field can be modified only when BUSY = 0.

Bits 15: 11 Reserved, must be kept at reset value.

Bits 10:8 **CSHT[2:0]**: Chip select high time

CSHT+1 defines the minimum number of CLK cycles which the chip select (nCS) must remain high between commands issued to the Flash memory.

- 0: nCS stays high for at least 1 cycle between Flash memory commands
- 1: nCS stays high for at least 2 cycles between Flash memory commands

...

- 7: nCS stays high for at least 8 cycles between Flash memory commands
- This field can be modified only when BUSY = 0.

Bits 7: 1 Reserved, must be kept at reset value.

Bit 0 **CKMODE**: Mode 0 / mode 3

This bit indicates the level that CLK takes between commands (when nCS = 1).  
 0: CLK must stay low while nCS is high (chip select released). This is referred to as mode 0.

1: CLK must stay high while nCS is high (chip select released). This is referred to as mode 3.

This field can be modified only when BUSY = 0.

### 23.5.3 QUADSPI status register (QUADSPI\_SR)

Address offset: 0x0008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This field gives the number of valid bytes which are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full. In memory-mapped mode and in automatic status polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is on going. This bit clears automatically when the operation with the Flash memory is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic polling mode when the unmasked received data matches the corresponding bits in the match register (QUADSPI\_PSMAR). It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after reads from the Flash memory are complete. It is cleared automatically as soon as threshold condition is no longer true.

In automatic polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

### 23.5.4 QUADSPI flag clear register (QUADSPI\_FCR)

Address offset: 0x000C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w1o	w1o		w1o	w1o

Bits 31: 4 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the QUADSPI\_SR register

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the QUADSPI\_SR register

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the QUADSPI\_SR register

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the QUADSPI\_SR register

### 23.5.5 QUADSPI data length register (QUADSPI\_DLR)

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 31:0 **DL[31: 0]**: Data length

Number of data to be retrieved (value+1) in indirect and status-polling modes. A value no greater than 3 (indicating 4 bytes) should be used for status-polling mode.  
 All 1s in indirect mode means undefined length, where QUADSPI will continue until the end of memory, as defined by FSIZE.  
 0x0000\_0000: 1 byte is to be transferred  
 0x0000\_0001: 2 bytes are to be transferred  
 0x0000\_0002: 3 bytes are to be transferred  
 0x0000\_0003: 4 bytes are to be transferred  
 ...  
 0xFFFF\_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred  
 0xFFFF\_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred  
 0xFFFF\_FFFF: undefined length -- all bytes until the end of Flash memory (as defined by FSIZE) are to be transferred. Continue reading indefinitely if FSIZE = 0x1F.  
 DL[0] is stuck at '1' in dual-flash mode (DFM = 1) even when '0' is written to this bit, thus assuring that each access transfers an even number of bytes.  
 This field has no effect when in memory-mapped mode (FMODE = 10).  
 This field can be written only when BUSY = 0.

### 23.5.6 QUADSPI communication configuration register (QUADSPI\_CCR)

Address offset: 0x0014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DDRM	DHHC	FRCM	SIOO	FMODE[1:0]		DMODE		Res.	DCYC[4:0]					ABSIZE	
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ABMODE		ADSIZE		ADMODE		IMODE		INSTRUCTION[7:0]							
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

- Bit 31 **DDRM**: Double data rate mode  
 This bit sets the DDR mode for the address, alternate byte and data phase:  
 0: DDR Mode disabled  
 1: DDR Mode enabled  
 This field can be written only when BUSY = 0.
- Bit 30 **DHHC**: DDR hold  
 Delay the data output by 1/4 of the QUADSPI output clock cycle in DDR mode:  
 0: Delay the data output using analog delay  
 1: Delay the data output by 1/4 of a QUADSPI output clock cycle.  
 This feature is only active in DDR mode.  
 This field can be written only when BUSY = 0.
- Bit 29 **FRCM**: Free Running Clock Mode  
 When this bit is set, the QUADSPI peripheral enters Free running clock mode regardless of the FMODE bits.  
 0: Normal mode  
 1: Free running clock mode  
 This bit can be written only when BUSY = 0.

Bit 28 **SIOO**: Send instruction only once mode  
See [Section 23.3.13: Sending the instruction only once on page 833](#). This bit has no effect when `IMODE = 00`.  
0: Send instruction on every transaction  
1: Send instruction only for the first command  
This field can be written only when `BUSY = 0`.

Bits 27:26 **FMODE[1:0]**: Functional mode  
This field defines the QUADSPI functional mode of operation.  
00: Indirect write mode  
01: Indirect read mode  
10: Automatic polling mode  
11: Memory-mapped mode  
This field can be written only when `BUSY = 0`.

Bits 25:24 **DMODE[1:0]**: Data mode  
This field defines the data phase's mode of operation:  
00: No data  
01: Data on a single line  
10: Data on two lines  
11: Data on four lines  
This field also determines the dummy phase mode of operation.  
This field can be written only when `BUSY = 0`.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **DCYC[4:0]**: Number of dummy cycles  
This field defines the duration of the dummy phase. In both SDR and DDR modes, it specifies a number of CLK cycles (0-31).  
This field can be written only when `BUSY = 0`.

Bits 17:16 **ABSIZE[1:0]**: Alternate bytes size  
This bit defines alternate bytes size:  
00: 8-bit alternate byte  
01: 16-bit alternate bytes  
10: 24-bit alternate bytes  
11: 32-bit alternate bytes  
This field can be written only when `BUSY = 0`.

Bits 15:14 **ABMODE[1:0]**: Alternate bytes mode  
This field defines the alternate-bytes phase mode of operation:  
00: No alternate bytes  
01: Alternate bytes on a single line  
10: Alternate bytes on two lines  
11: Alternate bytes on four lines  
This field can be written only when `BUSY = 0`.

Bits 13:12 **ADSIZE[1:0]**: Address size  
This bit defines address size:  
00: 8-bit address  
01: 16-bit address  
10: 24-bit address  
11: 32-bit address  
This field can be written only when `BUSY = 0`.

Bits 11:10 **ADMODE[1:0]**: Address mode  
 This field defines the address phase mode of operation:  
 00: No address  
 01: Address on a single line  
 10: Address on two lines  
 11: Address on four lines  
 This field can be written only when BUSY = 0.

Bits 9:8 **IMODE[1:0]**: Instruction mode  
 This field defines the instruction phase mode of operation:  
 00: No instruction  
 01: Instruction on a single line  
 10: Instruction on two lines  
 11: Instruction on four lines  
 This field can be written only when BUSY = 0.

Bits 7: 0 **INSTRUCTION[7: 0]**: Instruction  
 Instruction to be send to the external SPI device.  
 This field can be written only when BUSY = 0.

### 23.5.7 QUADSPI address register (QUADSPI\_AR)

Address offset: 0x0018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31 0]**: Address  
 Address to be send to the external Flash memory  
 Writes to this field are ignored when BUSY = 0 or when FMODE = 11 (memory-mapped mode).  
 In dual flash mode, ADDRESS[0] is automatically stuck to '0' as the address should always be even

### 23.5.8 QUADSPI alternate bytes registers (QUADSPI\_ABR)

Address offset: 0x001C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 0 **ALTERNATE[31: 0]**: Alternate Bytes

Optional data to be send to the external SPI device right after the address.  
This field can be written only when BUSY = 0.

### 23.5.9 QUADSPI data register (QUADSPI\_DR)

Address offset: 0x0020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 0 **DATA[31: 0]**: Data

Data to be sent/received to/from the external SPI device.

In indirect write mode, data written to this register is stored on the FIFO before it is sent to the Flash memory during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect read mode, reading this register gives (via the FIFO) the data which was received from the Flash memory. If the FIFO does not have as many bytes as requested by the read operation and if BUSY=1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic polling mode, this register contains the last data read from the Flash memory (without masking).

Word, halfword, and byte accesses to this register are supported. In indirect write mode, a byte write adds 1 byte to the FIFO, a halfword write 2, and a word write 4. Similarly, in indirect read mode, a byte read removes 1 byte from the FIFO, a halfword read 2, and a word read 4. Accesses in indirect mode must be aligned to the bottom of this register: a byte read must read DATA[7:0] and a halfword read must read DATA[15:0].

### 23.5.10 QUADSPI polling status mask register (QUADSPI\_PSMKR)

Address offset: 0x0024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 0 **MASK[31: 0]**: Status mask

Mask to be applied to the status bytes received in polling mode.

For bit n:

0: Bit n of the data received in automatic polling mode is masked and its value is not considered in the matching logic

1: Bit n of the data received in automatic polling mode is unmasked and its value is considered in the matching logic

This field can be written only when BUSY = 0.

### 23.5.11 QUADSPI polling status match register (QUADSPI\_PSMAR)

Address offset: 0x0028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 0 **MATCH[31: 0]**: Status match

Value to be compared with the masked status register to get a match.

This field can be written only when BUSY = 0.

### 23.5.12 QUADSPI polling interval register (QUADSPI\_PIR)

Address offset: 0x002C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 16 Reserved, must be kept at reset value.

Bits 15: 0 **INTERVAL[15: 0]**: Polling interval

Number of CLK cycles between to read during automatic polling phases.  
 This field can be written only when BUSY = 0.

### 23.5.13 QUADSPI low-power timeout register (QUADSPI\_LPTR)

Address offset: 0x0030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31: 16 Reserved, must be kept at reset value.

Bits 15: 0 **TIMEOUT[15: 0]**: Timeout period

After each access in memory-mapped mode, the QUADSPI prefetches the subsequent bytes and holds these bytes in the FIFO. This field indicates how many CLK cycles the QUADSPI waits after the FIFO becomes full until it raises nCS, putting the Flash memory in a lower-consumption state.  
 This field can be written only when BUSY = 0.

23.5.14 QUADSPI register map

Table 185. QUADSPI register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2](#) for the register boundary addresses.

## 24 Delay block (DLYB)

### 24.1 Introduction

The delay block (DLYB) is used to generate an output clock which is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or QUADSPI interface.

The delay is voltage- and temperature-dependent, which may require the application to re-configure and recenter the output clock phase with the receive data.

### 24.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 to 208 MHz
- Up to 12 oversampling phases.

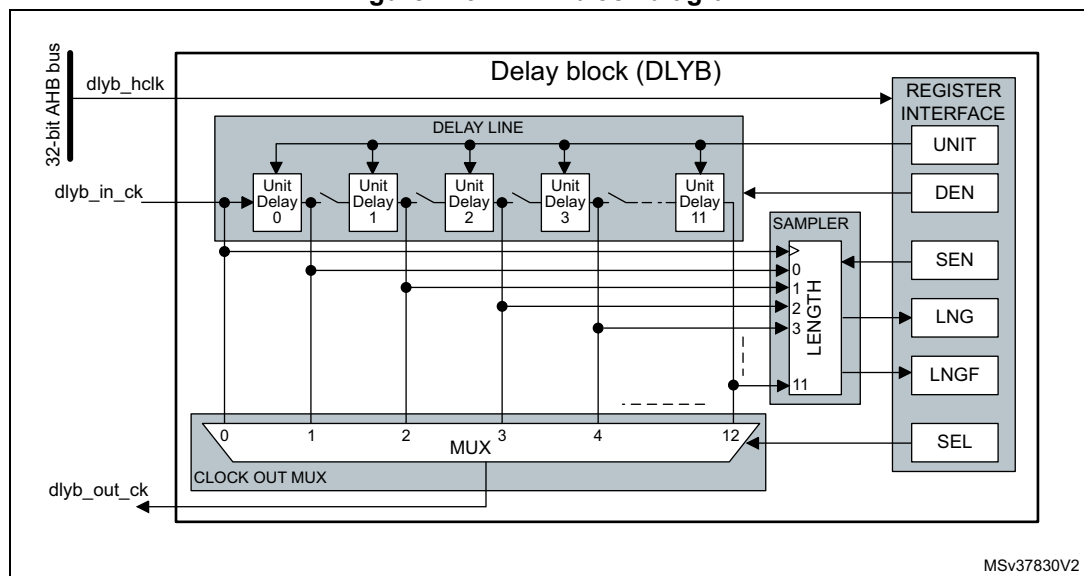

### 24.3 DLYB functional description

#### 24.3.1 DLYB diagram

The delay block includes of the following sub-blocks:

- Register interface block providing AHB access to the Delay Block registers.
- Delay line supporting the unit delays.
- Delay line length sampling
- Output clock selection multiplexer

Figure 123. DLYB block diagram

### 24.3.2 DLYB pins and internal signals

Table 186 lists the DLYB internal signals.

**Table 186. DLYB internal input/output signals**

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

### 24.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB\_CR register (see [Section 24.4.1: DLYB control register \(DLYB\\_CR\)](#)). The length sampler is enabled through the SEN bit in DLYB\_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT bits in DLYB\_CFGR register (see [Section 24.4.2: DLYB configuration register \(DLYB\\_CFGR\)](#)). Note that the UNIT bits can be programmed only when the output clock is disabled (SEN = '1').

When the delay block is enabled, the output clock phase is selected through the SEL bit in DLYB\_CFGR register. Note that SEL can be programmed only when the output clock is disabled (SEN = '1').

Before dephasing the output clock, the delay line length shall be configured to one input clock period. The delay line length can be configured by enabling the length sampler through the SEN bit, which gives access to the delay line length (LNG bits) and Length valid flag (LNGF) in DLYB\_CFGR.

Once the delay line length has been configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL bits. The output clock is only available on the selected phase when SEN is set to '0'.

Table 187. gives a summary of the delay block control.

**Table 187. Delay block control**

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don't care	Don't care	Don't care	Don't care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay <sup>(1)</sup>	Output clock phase <sup>(2)</sup>	Don't care	Don't care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = '1'.

2. The output clock phase can only be changed when SEN = '1'.

### 24.3.4 Delay line length configuration procedure

LNG bits are used to determine the delay line length with respect to the input clock period. The length shall be configured so that one full input clock period is covered by the delay line length.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to '1'.
2. Enable the length sampling by setting SEN bit to '1'.
3. Enable all delay cells by setting SEL bits to 12.
4. For UNIT = 0 to 127 (this step must be repeated until the delay line length is configured):
  - a) Update the UNIT value and wait till the length flag LNGF is set to '1'.
  - b) Read LNG bits.  
If  $(\text{LNG}[10:0] > 0)$  and  $(\text{LNG}[11] \text{ or } \text{LNG}[10] = 0)$ , the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period.
  - For N = 10 to 0:  
If  $\text{LNG}[N] = '1'$ , the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to '0'.

### 24.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL bits by setting SEN bit to '1'.
2. Program SEL bits with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to '0'.

## 24.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

### 24.4.1 DLYB control register (DLYB\_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **SEN**: Sampler length enable bit

0: Sampler length and register access to UNIT and SEL disabled, output clock enabled.

1: Sampler length and register access to UNIT and SEL enabled, output clock disabled.

Bit 0 **DEN**: Delay block enable bit

0: Delay block disabled.

1: Delay block enabled.

### 24.4.2 DLYB configuration register (DLYB\_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT							Res.	Res.	Res.	Res.	SEL			
	rw	rw	rw	rw	rw							rw	rw	rw	rw

- Bit 31 **LNGF**: Length valid flag  
 This flag indicates when the delay line length value contained in LNG bits is valid after UNIT bits changed.  
 0: Length value in LNG is not valid.  
 1: Length value in LNG is valid.
- Bits 30:28 Reserved, must be kept at reset value
- Bits 27:16 **LNG**: Delay line length value  
 These bits reflect the 12 unit delay values sampled at the rising edge of the input clock.  
 The value is only valid when LNGF = '1'.
- Bit 15 Reserved, must be kept at reset value
- Bits 14:8 **UNIT**: Delay Defines the delay of a Unit delay cell.  
 These bits can only be written when SEN = '1'.  
 Unit delay = Initial delay + UNIT x delay step
- Bits 7:4 Reserved, must be kept at reset value
- Bits 3:0 **SEL**: Select the phase for the Output clock.  
 These bits can only be written when SEN = '1'.  
 Output clock phase = Input clock + SEL x Unit delay

### 24.4.3 DLYB register map

Table 188. DLYB register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 25 Analog-to-digital converters (ADC)

### 25.1 Introduction

This section describes the implementation of up to 3 ADCs

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).
- ADC3 is instantiated separately.

Each ADC consists of a 16-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

## 25.2 ADC main features

- High-performance features
  - Up to 2x ADCs which can operate in dual mode
  - 16, 14, 12, 10 or 8-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Can manage Single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Self-calibration (both offset and the linearity)
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by GP-DMA for regular channel conversions with FIFO
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024x
  - Programmable data right and left shift
- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)
- Each ADC features an external analog input channel
  - Up to 6 fast channels from dedicated GPIO pads
  - Up to 14 slow channels from dedicated GPIO pads
- In addition, there are five internal dedicated channels
  - The internal reference voltage ( $V_{REFINT}$ ), connected to ADC3
  - The internal temperature sensor ( $V_{TS}$ ), connected to ADC3
  - The  $V_{BAT}$  monitoring channel ( $V_{BAT}/4$ ), connected to ADC3
  - The internal DAC channel 1 and channel 2, connected to ADC2
- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels

- Single mode converts selected inputs once per trigger
- Continuous mode converts selected inputs continuously
- Discontinuous mode
- Dual ADC mode for ADC1 and 2
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC supply requirements: 1.62 to 3.6 V
- ADC input range:  $V_{REF-} \leq V_{IN} \leq V_{REF+}$

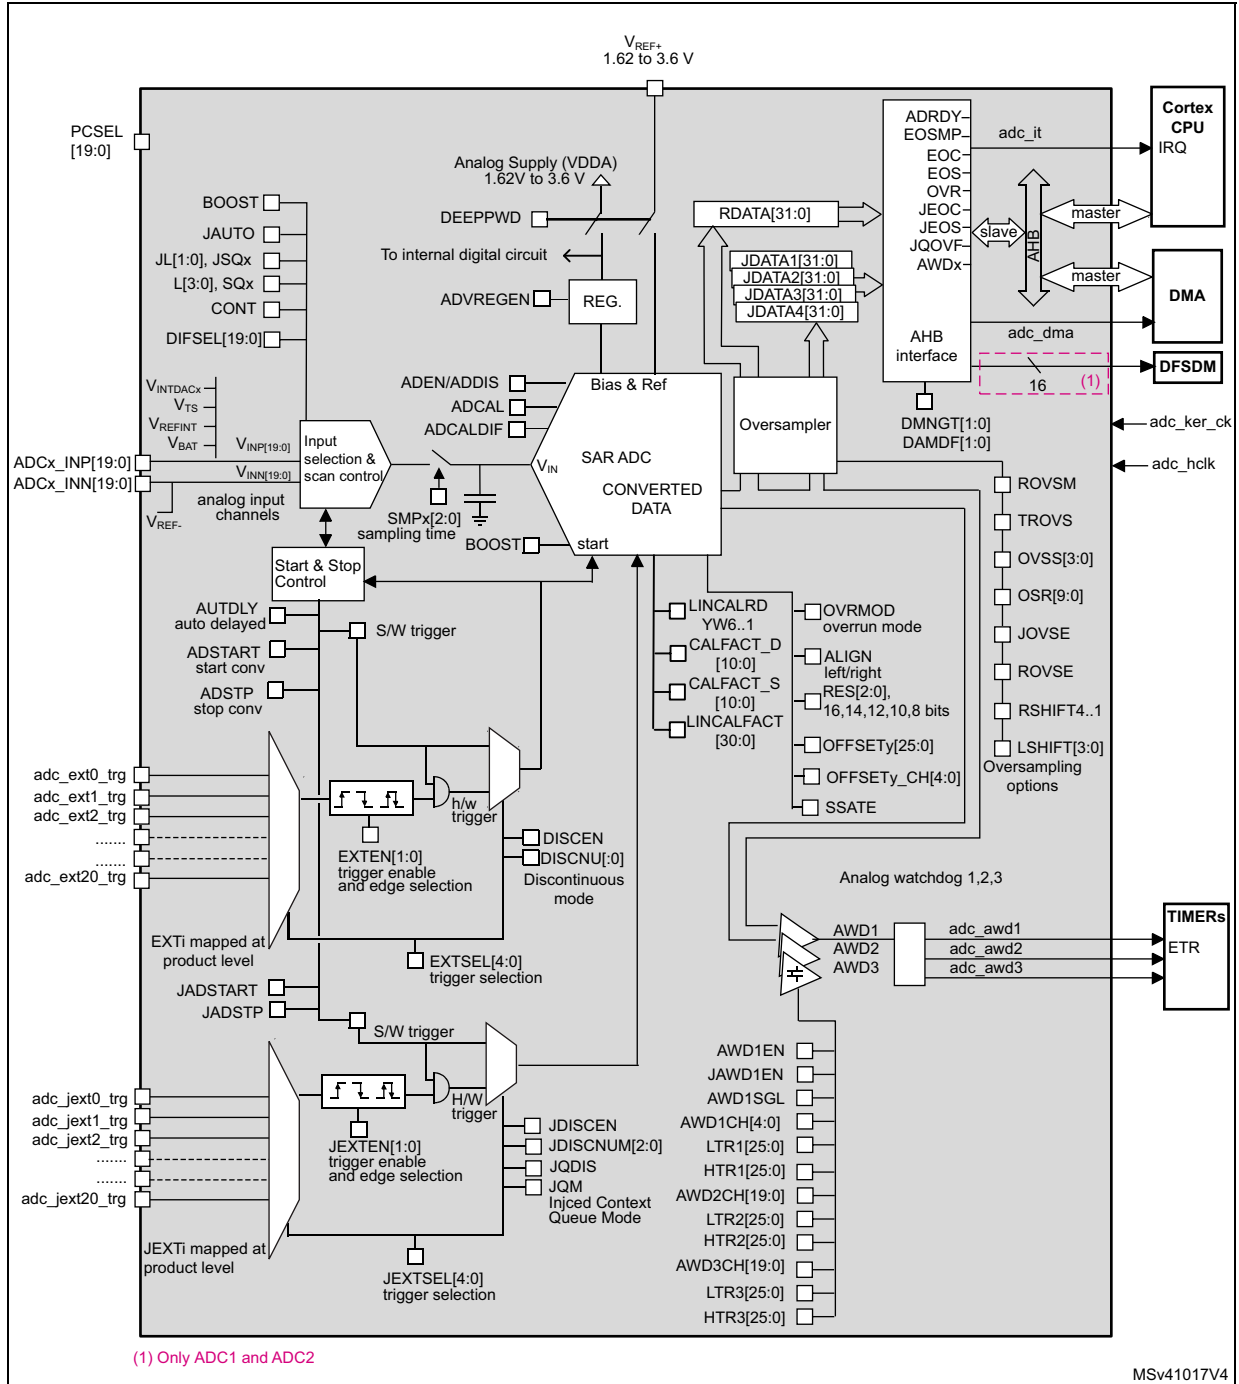

*Figure 124* shows the block diagram of one ADC.

## 25.3 ADC functional description

### 25.3.1 ADC block diagram

Figure 124 shows the ADC block diagram and Table 190 gives the ADC pin description.

Figure 124. ADC block diagram

25.3.2 ADC pins and internal signals

Table 189. ADC internal signals

Internal signal name	Signal type	Description
adc_ext_trg[20:0]	Digital inputs	Up to 21 external trigger inputs for the regular conversions (can be connected to on-chip timers). These inputs are shared between the ADC master and the ADC slave.
adc_jext_trg[20:0]	Digital inputs	Up to 21 external trigger inputs for the injected conversions (can be connected to on-chip timers). These inputs are shared between the ADC master and the ADC slave.
adc_awd1 adc_awd2 adc_awd3	Digital output	Internal analog watchdog output signal connected to on-chip timers. (x = Analog watchdog number 1,2,3)
V <sub>TS</sub>	Analog input	Output voltage from internal temperature sensor
V <sub>REFINT</sub>	Analog input	Output voltage from internal reference voltage
V <sub>BAT</sub>	Analog input	External battery voltage supply
adc_it	Digital output	ADC interrupt
adc_hclk	Digital input	AHB clock
adc_ker_ck	Digital input	ADC kernel clock
adc_dma	Digital output	ADC DMA requests

Table 190. ADC pins

Name	Signal type	Comments
V <sub>REF+</sub>	Input, analog reference positive	The higher/positive reference voltage for the ADC, $1.62\text{ V} \leq V_{REF+} \leq V_{DDA}$
V <sub>DDA</sub>	Input, analog supply	Analog power supply equal V <sub>DDA</sub> : $1.62\text{ V} \leq V_{DDA} \leq 3.6\text{ V}$
V <sub>REF-</sub>	Input, analog reference negative	The lower/negative reference voltage for the ADC, $V_{REF-} = V_{SSA}$
V <sub>SSA</sub>	Input, analog supply ground	Ground for analog power supply equal to V <sub>SS</sub>
V <sub>INP</sub> [19:0]	Positive input analog channels for each ADC	Connected either to external channels: ADC_INP <i>i</i> or internal channels.
V <sub>INN</sub> [19:0]	Negative input analog channels for each ADC	Connected to V <sub>REF-</sub> or external channels: ADC_INN <i>i-1</i>

Table 190. ADC pins (continued)

Name	Signal type	Comments
ADCx_INP[19:0]	External analog input signals	Up to 20 analog input channels (x = ADC number = 1,2 or 3): – ADCx_INP[0:5] fast channels – ADCx_INP[6:19] slow channels
ADCx_INN[19:0]		Up to 20 analog input channels (x = ADC number = 1,2 or 3): – ADCx_INN[0:5] fast channels – ADCx_INN[6:19] slow channels
PCSEL[19:0]	Output, prechannel selection control signal	Connected to GPIO to select the channel in advance

### 25.3.3 Clocks

#### Dual clock domain architecture

The dual clock-domain architecture means that the ADCs clock is independent from the AHB bus clock.

The input clock is the same for the three ADCs and can be selected between two different clock sources (see [Figure 125: ADC clock scheme](#)):

1. The ADC clock can be a specific clock source, named `adc_ker_ck` which is independent and asynchronous with the AHB clock.  
It can be configured in the RCC (refer to RCC Section for more information on how to generate the ADC clock (`adc_ker_ck`) dedicated clock).  
To select this scheme, CKMODE[1:0] bits of the ADCx\_CCR register must be reset.
2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).  
To select this scheme, CKMODE[1:0] bits of the ADCx\_CCR register must be different from "00".

*Note:* For option b), a prescaling factor of 1 (CKMODE[1:0]=01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC\_CFGR register).

Option a) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx\_CCR register.

Option b) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the product datasheet.

Figure 125. ADC clock scheme

1. Refer to the RCC section to see how `adc_hclk` and `adc_ker_ck` can be generated.

**Clock ratio constraint between ADC clock and AHB clock**

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- $F_{HCLK} \geq F_{ADC} / 4$  if the resolution of all channels are 16-bit, 14-bit, 12-bit or 10-bit
- $F_{HCLK} \geq F_{ADC} / 3$  if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)

**BOOST bit control**

There is ADC boost control bit `BOOST` in the `ADCx_CR` register.

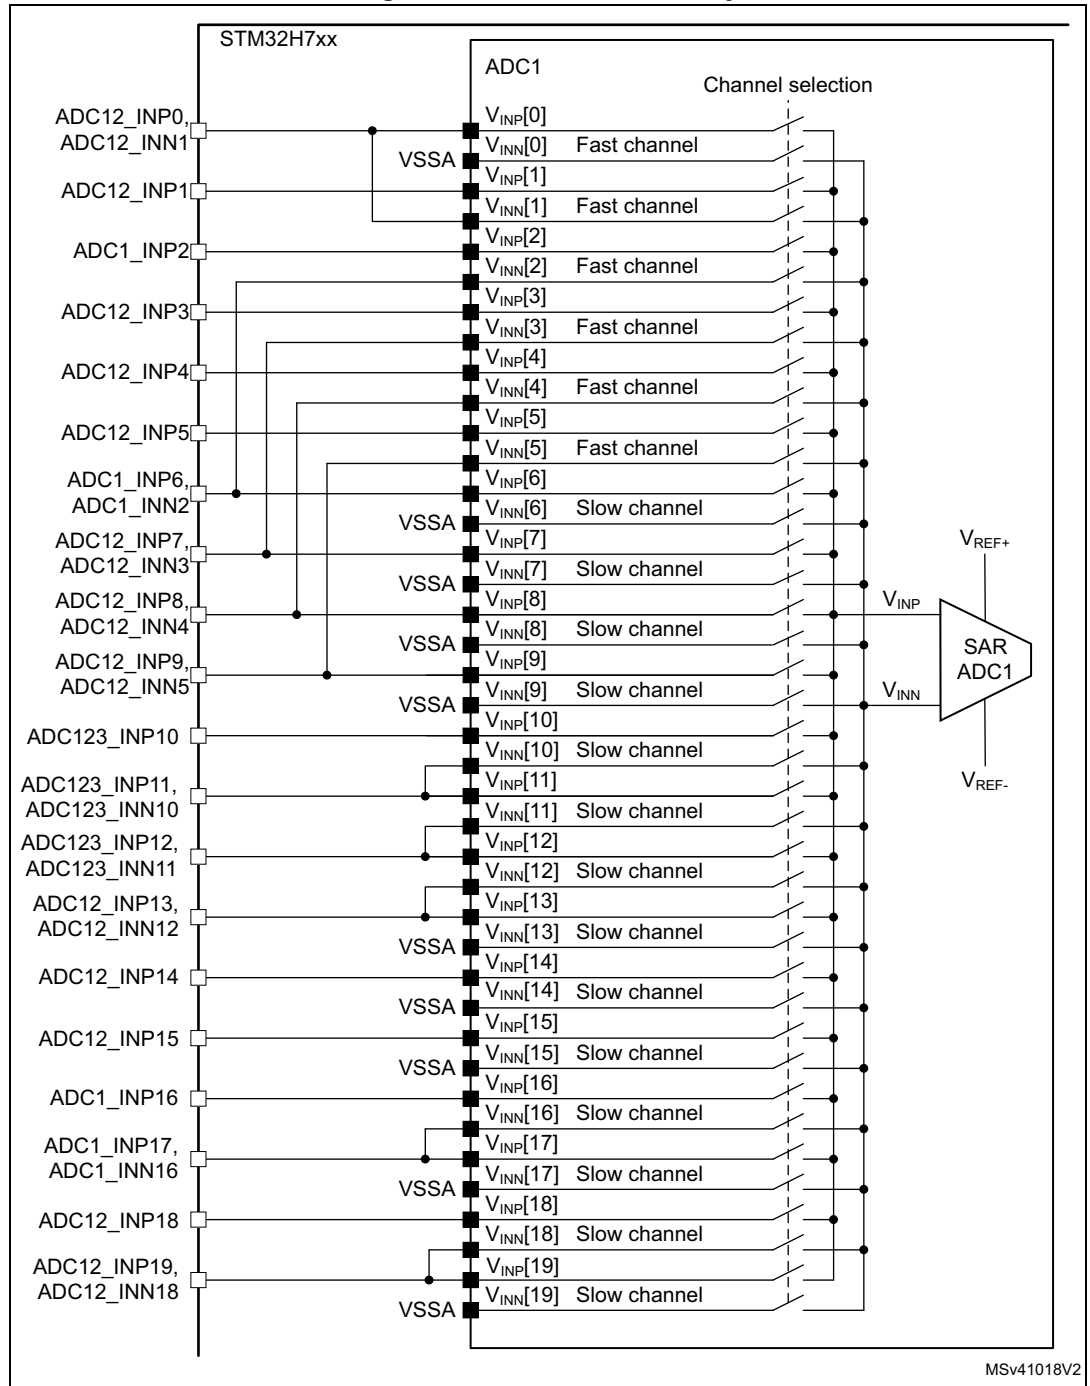

This bit must be set when ADC clock is more than 20 MHz. When ADC clock is less than 20 MHz, this bit can be cleared to save power.

### 25.3.4 ADC1/2/3 connectivity

ADC1 and ADC2 are tightly coupled and share some external channels as described in the following figures.

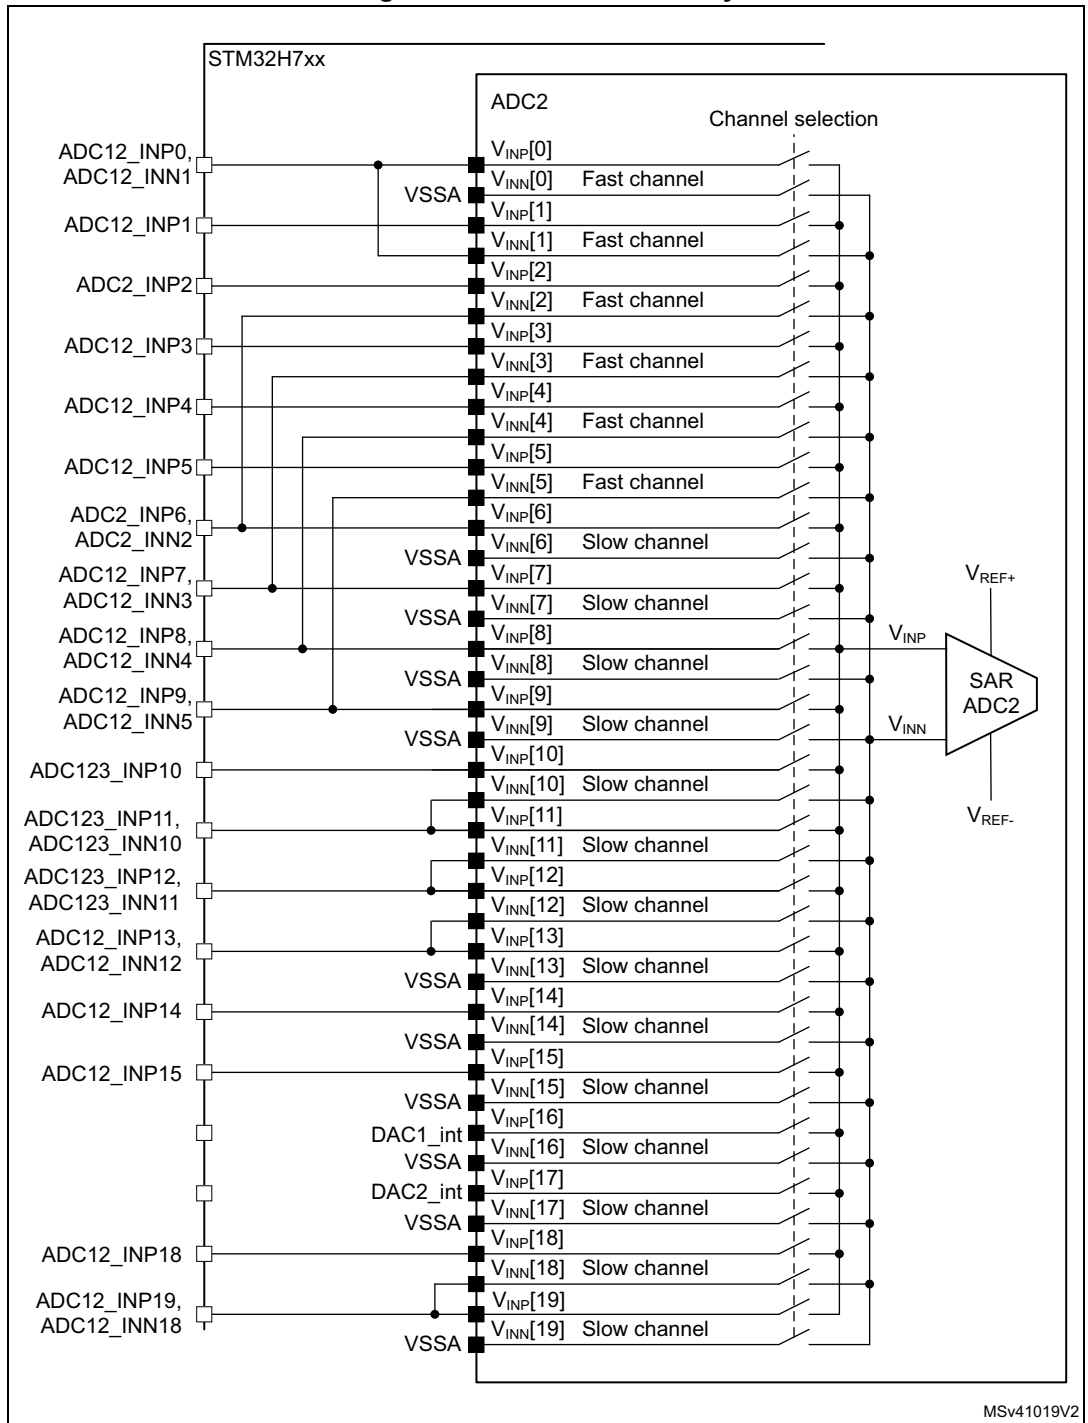

ADC3 is instantiated separately, but some inputs are shared with ADC1 and ADC2.

Figure 126. ADC1 connectivity

1. ADCx\_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.

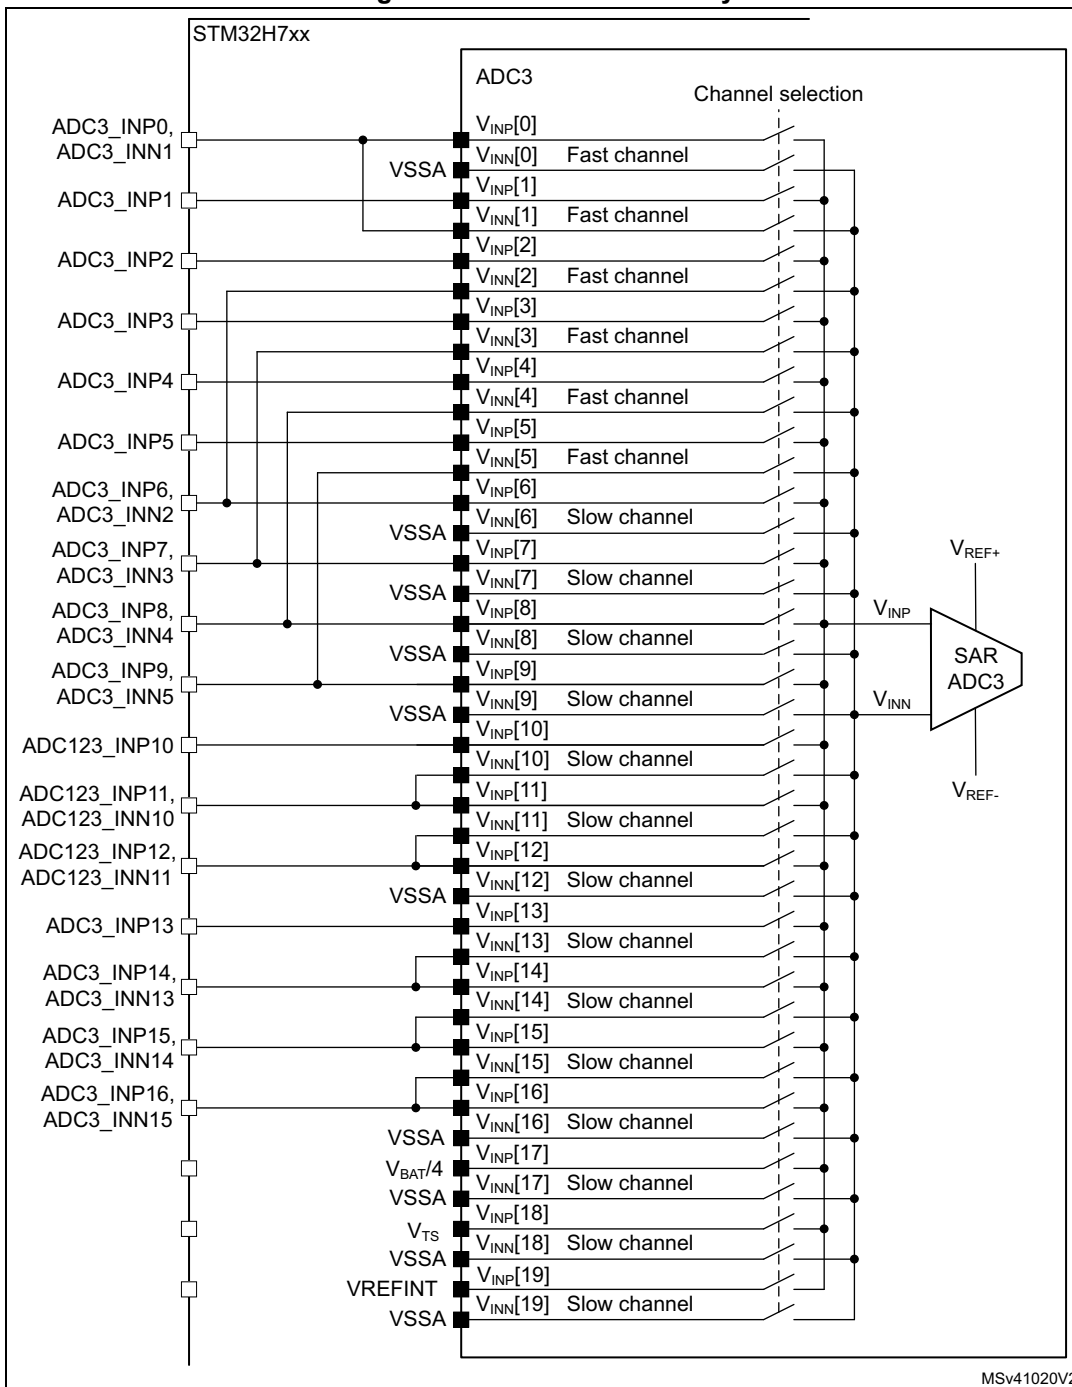

Figure 127. ADC2 connectivity

1. ADCx\_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.

Figure 128. ADC3 connectivity

1. ADCx\_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.

### 25.3.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

### 25.3.6 ADC Deep-Power-Down Mode (DEEPPWD) & ADC Voltage Regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADCx\_CR register).

To start ADC operations, it is first needed to exit deep-power-down mode by clearing bit DEEPPWD=0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN=1 into ADCx\_CR register. The software must wait for the startup time of the ADC voltage regulator ( $T_{\text{ADCVREG\_STUP}}$ ) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, please refer to device datasheet for  $T_{\text{ADCVREG\_STUP}}$  parameter.

After ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC deep-power-down mode by setting bit DEEPPWD=1 into ADCx\_CR register. This is particularly interesting before entering STOP mode.

*Note:* Writing DEEPPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

*Note:* When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC deep-power-down mode (DEEPPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to [Section 25.3.8: Calibration \(ADCAL, ADCALDIF, ADCALLIN, ADCx\\_CALFACT\)](#)).

### 25.3.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by writing into bits DIFSEL[19:0] in the ADCx\_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0).

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage  $V_{INP[i]}$  (positive input) and  $V_{REF-}$  (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage  $V_{INP[i]}$  (positive input) and  $V_{INN[i]}$  (negative input).

The output data for the differential mode is an unsigned data. When  $V_{INP[i]}$  is  $V_{REF-}$ ,  $V_{INN[i]}$  is  $V_{REF+}$ , the output data is 0x0000 (16-bit resolution mode), when  $V_{INP[i]}$  is  $V_{REF+}$ ,  $V_{INN[i]}$  is  $V_{REF-}$ , the output data is 0xFFFF.

$$\text{Converted value} = \frac{\text{ADC\_Full\_Scale}}{2} \times \left[ 1 + \frac{V_{INP} - V_{INN}}{V_{REF+}} \right]$$

When ADC is configured as differential mode, both input should be biased at  $V_{REF+} / 2$  voltage.

The input signal are supposed to be differential (common mode voltage should be fixed).

For a complete description of how the input channels are connected for each ADC, refer to [Figure 126: ADC1 connectivity](#) to [Figure 128: ADC3 connectivity](#).

**Caution:** When configuring the channel “i” in differential input mode, its negative input voltage is connected to  $V_{INN[i]}$ . As a consequence, channel “i+n”, which is connected to  $V_{INN[i]}$ , should not be converted at same time by different ADCs. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable.

### 25.3.8 Calibration (ADCAL, ADCALDIF, ADCALLIN, ADCx\_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 11-bits of offset or 160-bits of linearity and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the systematic errors which may vary from chip to chip and allows to compensate offset and linearity deviation.

The calibration factor for the offset to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF=0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF=1 before launching a calibration which will be applied for differential input conversions.

The linearity correction must be done once only, regardless of single / differential configuration.

- Write ADCALLIN=1 before launching a calibration which will run the linearity calibration same time as the offset calibration.
- Write ADCALLIN=0 before launching a calibration which will not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting bit ADCAL=1. Calibration can only be initiated when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT\_S[10:0] or CALFACT\_D[10:0] of ADCx\_CALFACT register (depending on single-ended or differential input calibration). The 160-bit linearity calibration factor can be accessed using the ADCx\_CALFACT2 register with ADEN set to 1.

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in STANDBY or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADCx\_CALFACT and ADCx\_CALFACT2 register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor will automatically be injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when  $V_{REF+}$  voltage changed more than 10%.

The calibration requires 131,072 ADC clock cycle for the linear calibration and 520 ADC clock cycle for the offset calibration.

### Software procedure to calibrate the ADC

1. Ensure DEEPPWD=0, ADVREGEN=1 and check that the ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (Single-ended input) or ADCALDIF=1 (Differential input). Select if Linearity calibration enable or not by ADCALLIN=1(enabled) or ADCALLIN=0(disabled).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The offset calibration factor can be read from ADCx\_CALFACT register.
7. The linearity calibration factor can be read from ADCx\_CALFACT2 register, following the procedure described in [Section : Linearity calibration reading procedure](#) (ADEN must be set to 1 prior to accessing ADCx\_CALFACT2 register).

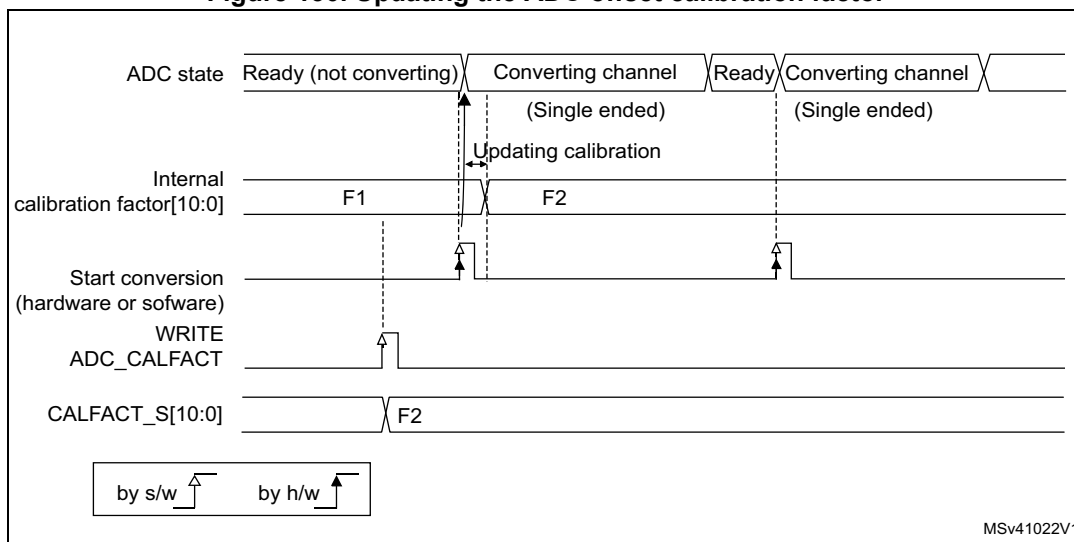

Figure 129. ADC calibration

**Software procedure to re-inject a calibration factor into the ADC**

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT\_S and CALFACT\_D with the new offset calibration factors.
3. Write LINCALFACT bits with the new linearity calibration factors, following the procedure described in [Section : Linearity calibration writing procedure](#).
4. When a conversion is launched, the calibration factor will be injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT\_S for single-ended input channel or bits CALFACT\_D for differential input channel.

Figure 130. Updating the ADC offset calibration factor

### Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0) and Linearity calibration enable (with ADCALLIN=1). This updates the registers CALFACT\_S[10:0] and LINCALFACT[159:0].
3. Calibrate the ADC in Differential input modes (with ADCALDIF=1) and Linearity calibration disable (with ADCALLIN=0). This updates the register CALFACT\_D[10:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration will automatically be injected into the analog ADC.

**Figure 131. Mixing single-ended and differential channels**

### Linearity calibration reading procedure

Once the calibration is done (ADCAL bit cleared by hardware) with ADCALLIN=1, the 160-bit linearity correction factor can be read using the ADCx\_CALFACT2 30-bit registers (6 read accesses are necessary).

The six LINCALRDYW1..6 control/status bits in ADCx\_CR are set when the calibration is complete. When ADEN is set to 1, clearing one of these bits launches the transfer of part of the linearity factor into the LINCALFACT[29:0] of the ADCx\_CALFACT2 register. The bit will be reset by hardware when the ADCx\_CALFACT2 register can be read (software must poll the bit until it is cleared). The complete procedure is as following:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that the ADC voltage regulator startup time has elapsed.
2. Set ADEN = 1 and wait until ADRDY=1.
3. Clear LINCALRDYW6 bit (Linearity calibration ready Word 6).
4. Poll LINCALRDYW6 bit until returned value is zero, indicating linearity correction bits[159:150] are available in ADCx\_CALFACT2[29:0]
5. Read ADCx\_CALFACT2[29:0]
6. Clear LINCALRDYW5 bit
7. Poll LINCALRDYW5 bit until returned value is zero, indicating linearity correction bits[149:120] are available in ADCx\_CALFACT2[29:0]
8. Read ADCx\_CALFACT2[29:0]
9. Clear LINCALRDYW4 bit
10. Poll LINCALRDYW4 bit until returned value is zero, indicating linearity correction bits[119:90] are available in ADCx\_CALFACT2[29:0]
11. Read ADCx\_CALFACT2[29:0]
12. Clear LINCALRDYW3 bit
13. Poll LINCALRDYW3 bit until returned value is zero, indicating linearity correction bits[89:60] are available in ADCx\_CALFACT2[29:0]
14. Read ADCx\_CALFACT2[29:0]
15. Clear LINCALRDYW2 bit
16. Poll LINCALRDYW2 bit until returned value is zero, indicating linearity correction bits[59:30] are available in ADCx\_CALFACT2[29:0]
17. Read ADCx\_CALFACT2[29:0]
18. Clear LINCALRDYW1 bit
19. Poll LINCALRDYW1 bit until returned value is zero, indicating linearity correction bits[29:0] are available in ADCx\_CALFACT2[29:0]
20. Read ADCx\_CALFACT2[29:0]

*Note:* The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

*The software can access the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).*

### Linearity calibration writing procedure

The six LINCALRDYW1..6 control/status bits in ADCx\_CR are reset when the calibration has not yet been done or a new linearity calibration factor have been rewritten. It is possible to force directly a linearity calibration factor or re-inject it using the following procedure:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed.
2. Set ADEN = 1 and wait until ADRDY=1.
3. Write ADCx\_CALFACT2[9:0] with previously saved linearity correction factor bits[159:150]
4. Set LINCALRDYW6 bit
5. Poll LINCALRDYW6 bit until returned value is one, indicating linearity correction bits[159:150] have been effectively written.
6. Write ADCx\_CALFACT2[29:0] with previously saved linearity correction factor bits[149:120]
7. Set LINCALRDYW5 bit
8. Poll LINCALRDYW5 bit until returned value is one, indicating linearity correction bits[149:120] have been effectively written.
9. Write ADCx\_CALFACT2[29:0] with previously saved linearity correction factor bits[119:90]
10. Set LINCALRDYW4 bit
11. Poll LINCALRDYW4 bit until returned value is one, indicating linearity correction bits[119:90] have been effectively written.
12. Write ADCx\_CALFACT2[29:0] with previously saved linearity correction factor bits[89:60]
13. Set LINCALRDYW3 bit
14. Poll LINCALRDYW3 bit until returned value is one, indicating linearity correction bits[89:60] have been effectively written.
15. Write ADCx\_CALFACT2[29:0] with previously saved linearity correction factor bits[59:30]
16. Set LINCALRDYW2 bit
17. Poll LINCALRDYW2 bit until returned value is one, indicating linearity correction bits[59:30] have been effectively written.
18. Write ADCx\_CALFACT2[29:0] with previously saved linearity correction factor bits[29:0]
19. Set LINCALRDYW1 bit
20. Poll LINCALRDYW1 bit until returned value is one, indicating linearity correction bits[29:0] have been effectively written.

*Note:* The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software is allowed to update the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

### 25.3.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in [Section 25.3.6: ADC Deep-Power-Down Mode \(DEEPPWD\) & ADC Voltage Regulator \(ADVREGEN\)](#).

Once DEEPPWD=0 and ADVREGEN=1, the ADC can be enabled and the ADC needs a stabilization time of  $t_{STAB}$  before it starts converting accurately, as shown in [Figure 132](#). Two control bits enable or disable the ADC:

- ADEN=1 enables the ADC. The flag ADRDY will be set once the ADC is ready for operation.
- ADDIS=1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to [Section 25.3.19: Conversion on external trigger and trigger polarity \(EXTSEL, EXTEN, JEXTSEL, JEXTEN\)](#)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.

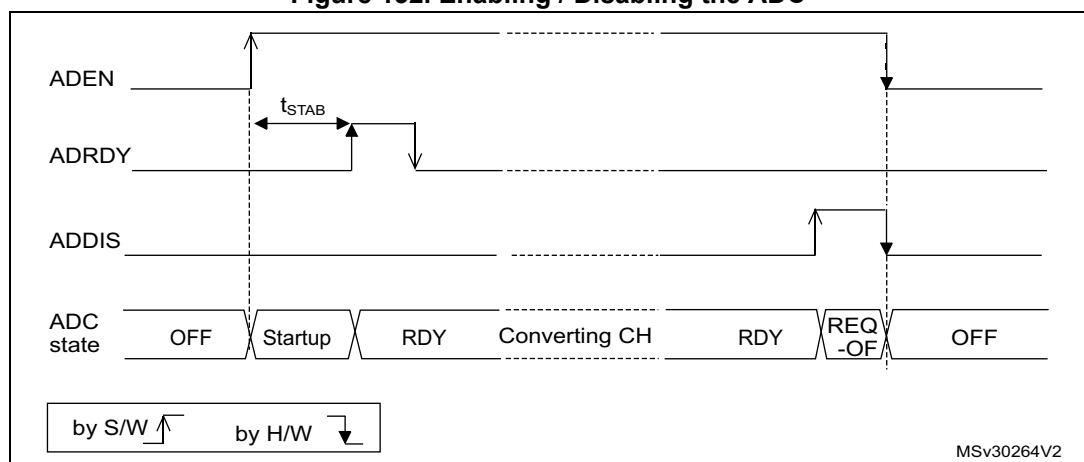

#### Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC\_ISR register by writing '1'.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC\_ISR register by writing '1' (optional).

#### Software procedure to disable the ADC

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS will automatically be reset once ADEN=0).

Figure 132. Enabling / Disabling the ADC

### 25.3.10 Constraints when writing the ADC control bits

The software can write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the control bits DIFSEL in the ADCx\_DIFSEL register, ADCx\_CCR register and the control bits ADCAL and ADEN in the ADCx\_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADCx\_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADCx\_CFGR, ADCx\_SMPRy, ADCx\_TRy, ADCx\_SQRy, ADCx\_JDRy, ADCx\_OFRRy, ADCx\_OFCHRRy and ADCx\_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software can write ADSTP or JADSTP control bits in the ADCx\_CR register only if the ADC is enabled and eventually converting and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADCx\_JSQR at any time, when the ADC is enabled (ADEN=1).

*Note:* There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADCx\_CR register).

### 25.3.11 Channel selection (SQRx, JSQRx)

There are up to 20 multiplexed channels per ADC:

- 6 fast analog inputs coming from Analog PADs and GPIO pads (ADCx\_INP/INN[0..5])
- Up to 14 slow analog inputs coming from GPIO pads (ADCx\_INP/INN[6..19]).
- The ADCs are connected to 5 internal analog inputs:
  - the internal reference voltage ( $V_{REFINT}$ ) is connected to ADC3\_INP/INN19.
  - the internal temperature sensor ( $V_{TS}$ ) is connected to ADC3\_INP/INN18.
  - the  $V_{BAT}$  monitoring channel ( $V_{BAT}/4$ ) is connected to ADC3\_INP/INN17.
  - DAC internal channel 1, connected to ADC2\_INP/INN16
  - DAC internal channel 2, connected to ADC2\_INP/INN17

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC\_INP/INN3, ADC\_INP/INN8, ADC\_INP/INN2, ADC\_INP/INN2, ADC\_INP/INN0, ADC\_INP/INN2, ADC\_INP/INN2, ADC\_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADCx\_SQR registers. The

total number of conversions in the regular group must be written in the L[3:0] bits in the ADCx\_SQR1 register.

- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADCx\_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADCx\_JSQR register.

ADCx\_SQR registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to [Section 25.3.18: Stopping an ongoing conversion \(ADSTP, JADSTP\)](#)).

It is possible to modify the ADCx\_JSQR registers on-the-fly while injected conversions are occurring. Refer to [Section 25.3.22: Queue of context for injected conversions](#)

### Temperature sensor, V<sub>REFINT</sub> and V<sub>BAT</sub> internal channels

The temperature sensor V<sub>TS</sub> is connected to channel ADC3 V<sub>INP</sub>[18].

The V<sub>BAT</sub> channel is connected to channel ADC3 V<sub>INP</sub>[17].

The internal reference voltage V<sub>REFINT</sub> is connected to ADC3 V<sub>INP</sub>[19].

*Note:* To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, TSEN or VBATEN in the ADCx\_CCR registers.

### 25.3.12 Prechannel selection register (ADCx\_PCSEL)

For each channel selected through SQRx or JSQRx, the corresponding ADCx\_PCSEL bit must be previously configured.

This ADCx\_PCSEL bit controls the transmission gate integrated in the IO level. The ADC input MUX selects the ADC input according to the SQRx and JSQRx with very high speed, the transmission gate integrated in the IO cannot react as fast as ADC mux do. To avoid the delay on transmission gate control on IO, it is necessary to pre select the input channels which will be selected in the SQRx, JSQRx.

The selection is based on the V<sub>INP</sub>[i] of the each ADC input. If ADC1 will convert the ADC123\_INP2(V<sub>INP</sub>[2]) as differential mode, ADC123\_INP6(V<sub>INP</sub>[6]) also need to be selected in ADCx\_PCSEL.

Some ADC input are connected several V<sub>INP</sub>[i] of the ADCx. Those input are ORed by ADCx\_PCSEL register bits.

### 25.3.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADCx\_SMPR1 and ADCx\_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 8.5 ADC clock cycles
- SMP = 011: 16.5 ADC clock cycles
- SMP = 100: 32.5 ADC clock cycles
- SMP = 101: 64.5 ADC clock cycles
- SMP = 110: 387.5 ADC clock cycles
- SMP = 111: 810.5 ADC clock cycles

The total conversion time is calculated as follows:

$$T_{\text{CONV}} = \text{Sampling time} + 7.5 \text{ ADC clock cycles}$$

Example:

With  $F_{\text{adc\_ker\_ck}} = 24 \text{ MHz}$  and a sampling time of 1.5 ADC clock cycles:

$$T_{\text{CONV}} = (1.5 + 7.5) \text{ ADC clock cycles} = 9 \text{ ADC clock cycles} = 0.375 \mu\text{s} \text{ (14 bit mode for fast channels)}$$

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

### Constraints on the sampling time for fast and slow channels

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

### I/O analog switches voltage booster

The I/O analog switches resistance increases when the  $V_{\text{DDA}}$  voltage is too low. This requires to have the sampling time adapted accordingly (cf datasheet for electrical characteristics). This resistance can be minimized at low  $V_{\text{DDA}}$  by enabling an internal voltage booster with BOOSTEN bit in the SYSCFG\_CFGR1 register.

## 25.3.14 Single conversion mode (CONT=0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADCx\_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADCx\_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)  
ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADCx\_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADCx\_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

*Note:* To convert a single channel, program a sequence with a length of 1.

### 25.3.15 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically re-starts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADCx\_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADCx\_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

*Note:* To convert a single channel, program a sequence with a length of 1.

*It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.*

*Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to [Auto-injection mode](#) section).*

### 25.3.16 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:

- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN != 0x0

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:

- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN != 0x0

*Note: In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).*

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

- In single mode with software trigger (CONT=0, EXTEN=0x0)
  - at any end of conversion sequence (EOS =1)
- In discontinuous mode with software trigger (CONT=0, DISCEN=1, EXTEN=0x0)
  - at end of conversion (EOC=1)
- In all other cases (CONT=x, EXTEN=x)
  - after execution of the ADSTP procedure asserted by the software.

*Note: In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.*

*When a hardware trigger is selected in single mode (CONT=0 and EXTEN !=0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.*

JADSTART is cleared by hardware:

- in single mode with software injected trigger (JEXTEN=0x0)
  - at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN=1
- in all cases (JEXTEN=x)
  - after execution of the JADSTP procedure asserted by the software.

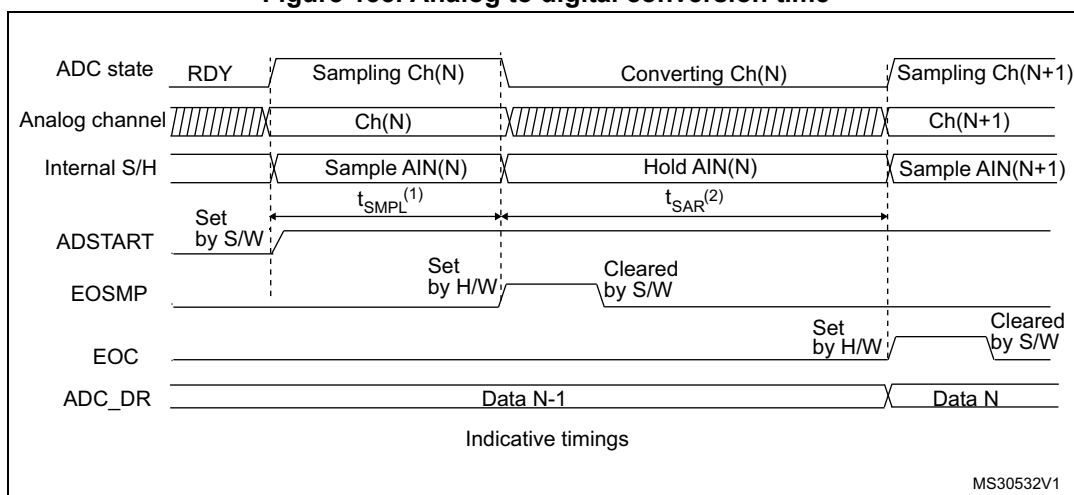

### 25.3.17 Timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$$T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [1.5_{\text{min}} + 7.5_{\text{[14bit]}}] \times T_{\text{adc\_ker\_ck}}$$

$$T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 62.5 \text{ ns}_{\text{min}} + 312.5 \text{ ns}_{\text{[14bit]}} = 375.0 \text{ ns (for } F_{\text{adc\_ker\_ck}} = 24 \text{ MHz)}$$

Figure 133. Analog to digital conversion time

1.  $T_{SMP}$  depends on SMP[2:0]
2.  $T_{SAR}$  depends on RES[2:0]

### 25.3.18 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP=1 and injected conversions ongoing by setting JADSTP=1.

Stopping conversions will reset the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADCx\_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADCx\_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

*Note:* In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 134. Stopping ongoing regular conversions

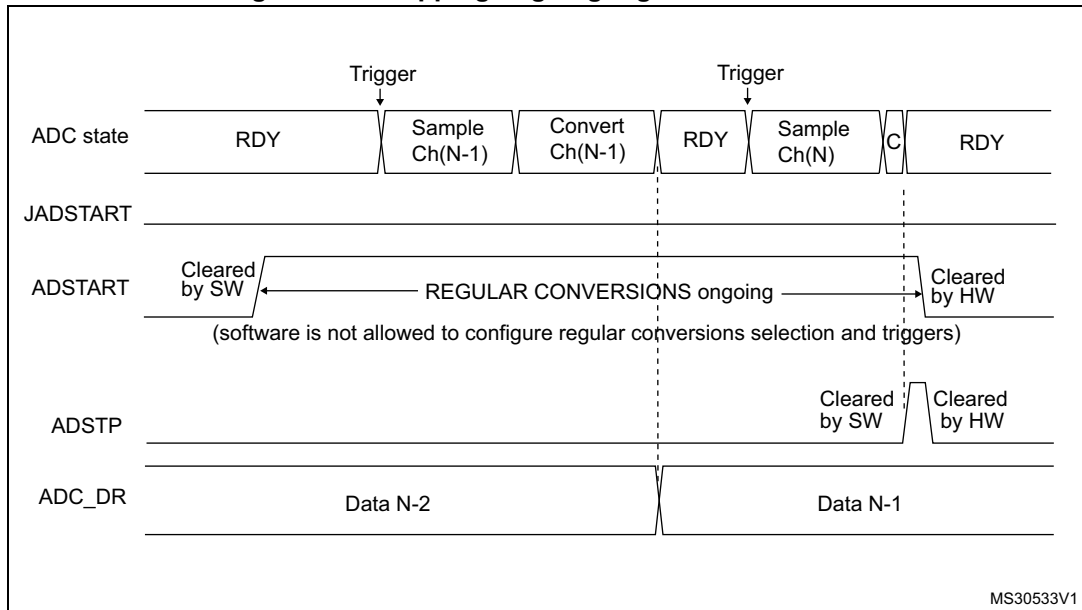

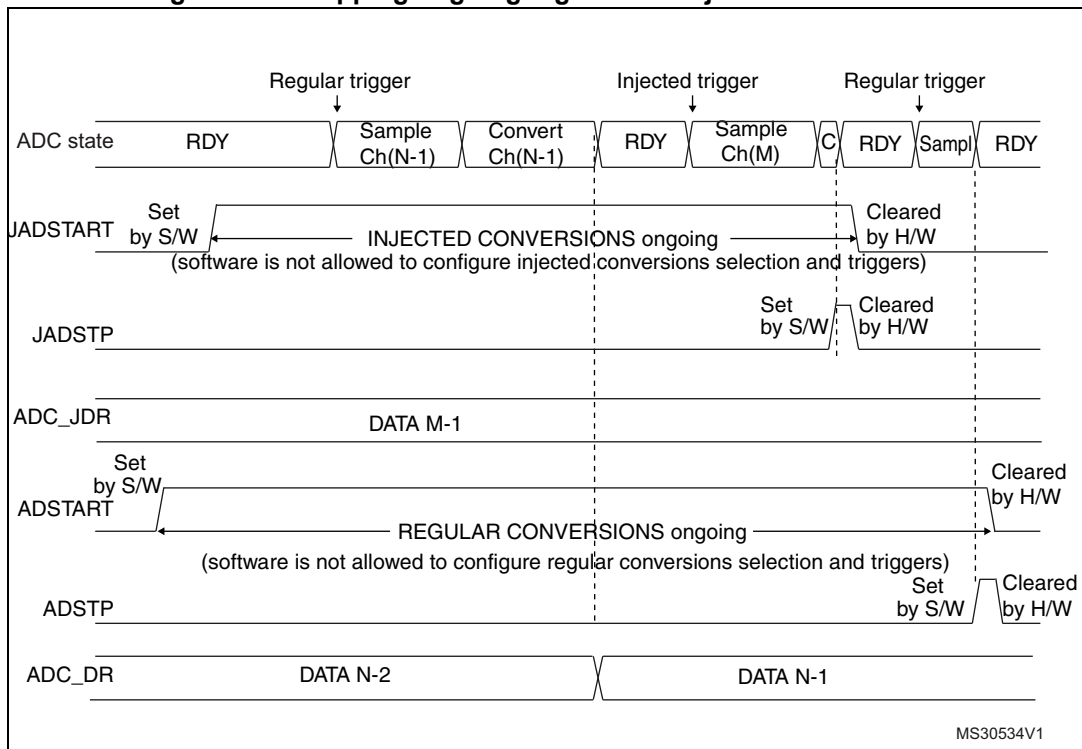

Figure 135. Stopping ongoing regular and injected conversions

### 25.3.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

- If bit ADSTART=0, any regular hardware triggers which occur are ignored.
- If bit JADSTART=0, any injected hardware triggers which occur are ignored.

[Table 191](#) provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

**Table 191. Configuring the trigger polarity for regular external triggers**

EXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

*Note:* The polarity of the regular trigger cannot be changed on-the-fly.

**Table 192. Configuring the trigger polarity for injected external triggers**

JEXTEN[1:0]	Source
00	– If JQDIS=1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled – If JQDIS=0 (Queue enabled), Hardware and software trigger detection disabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

*Note:* The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to [Section 25.3.22: Queue of context for injected conversions](#).

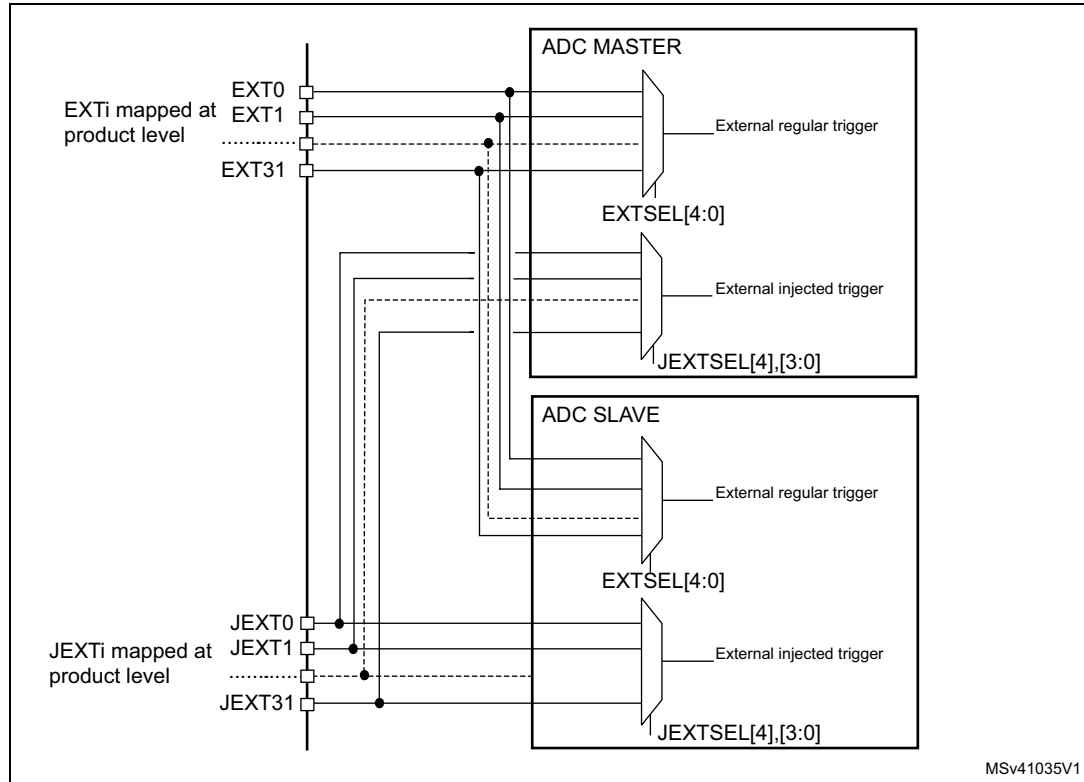

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which out of 21 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

*Note:* The regular trigger selection cannot be changed on-the-fly.  
 The injected trigger selection can be anticipated and changed on-the-fly. Refer to [Section 25.3.22: Queue of context for injected conversions on page 886](#)

Each ADC master shares the same input triggers with its ADC slave as described in [Figure 136](#).

**Figure 136. Triggers are shared between ADC master and ADC slave**

[Table 193](#) and [Table 194](#) give all the possible external triggers of the three ADCs for regular and injected conversion.

### 25.3.20 Injected channel management

#### Triggered injection mode

To use triggered injection, the JAUTO bit in the ADCx\_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADCx\_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADCx\_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence.

*Figure 137* shows the corresponding timing diagram.

*Note:* When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 20 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 21 ADC clock cycles.

**Auto-injection mode**

If the JAUTO bit in the ADCx\_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADCx\_SQR and ADCx\_JSQR registers.

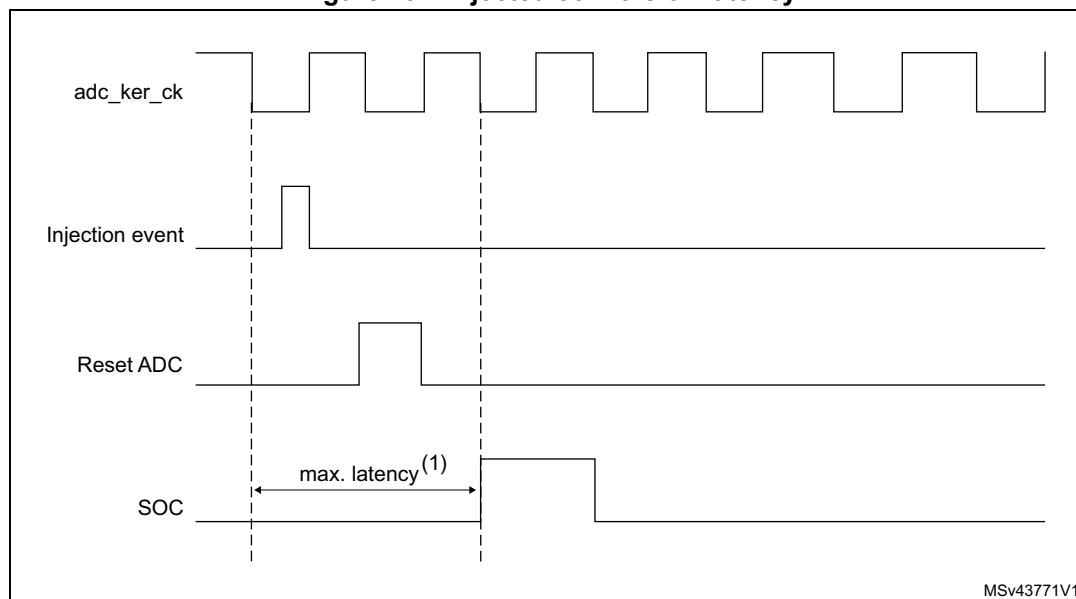

In this mode, the ADSTART bit in the ADCx\_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

*Note:* It is not possible to use both the auto-injected and discontinuous modes simultaneously. When the DMA is used for exporting regular sequencer's data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA\_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence will be stopped upon DMA Transfer Complete event.

**Figure 137. Injected conversion latency**

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

### 25.3.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

#### Regular group mode

This mode is enabled by setting the DISCEN bit in the ADCx\_CFGR register.

It is used to convert a short sequence (sub-group) of  $n$  conversions ( $n \leq 8$ ) that is part of the sequence of conversions selected in the ADCx\_SQRy registers. The value of  $n$  is specified by writing to the DISCNUM[2:0] bits in the ADCx\_CFGR register.

When an external trigger occurs, it starts the next  $n$  conversions selected in the ADCx\_SQR registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADCx\_SQR1 register.

Example:

- DISCEN=1,  $n=3$ , channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- DISCEN=0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - all the next trigger events will relaunch the complete sequence.

*Note:* When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than  $n$  conversions).

*When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.*

*It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN=1, CONT=1), the ADC behaves as if continuous mode was disabled.*

#### Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADCx\_CFGR register. It converts the sequence selected in the ADCx\_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where 'n' is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADCx\_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADCx\_JSQR register.

Example:

- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOP event is generated)
  - 2nd trigger: channel 2 converted (a JEOP event is generated)
  - 3rd trigger: channel 3 converted and a JEOP event + a JEOS event are generated
  - ...

*Note:* When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

*It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

### 25.3.22 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADCx\_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:

- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL[4:0] in ADCx\_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADCx\_JSQR register)

All the parameters of the context are defined into a single register ADCx\_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADCx\_CFGR:
  - If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence will be served according to the last active context.
  - If JQM=1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and

hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.

- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

*Note:* When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1<sup>st</sup> trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

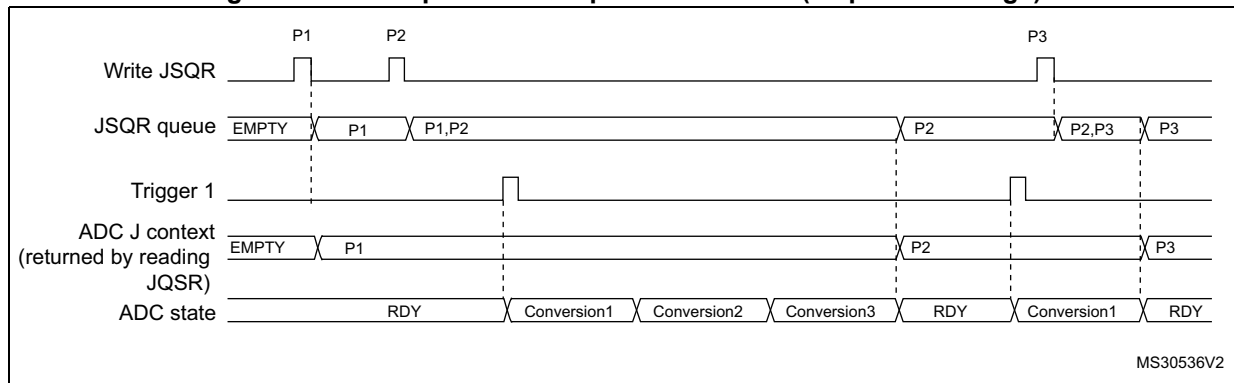

- 1<sup>st</sup> trigger, discontinuous. Sequence 1: context 1 consumed, 1<sup>st</sup> conversion carried out
- 2<sup>nd</sup> trigger, disc. Sequence 1: 2<sup>nd</sup> conversion.
- 3<sup>rd</sup> trigger, discontinuous. Sequence 1: 3<sup>rd</sup> conversion.
- 4<sup>th</sup> trigger, discontinuous. Sequence 2: context 2 consumed, 1<sup>st</sup> conversion carried out.
- 5<sup>th</sup> trigger, discontinuous. Sequence 2: 2<sup>nd</sup> conversion.
- 6<sup>th</sup> trigger, discontinuous. Sequence 2: 3<sup>rd</sup> conversion.

*Note:* When queue of context enabled (bit JQDIS=0), only hardware trigger can be used.

**Behavior when changing the trigger or sequence context**

The [Figure 138](#) and [Figure 139](#) show the behavior of the context Queue when changing the sequence or the triggers.

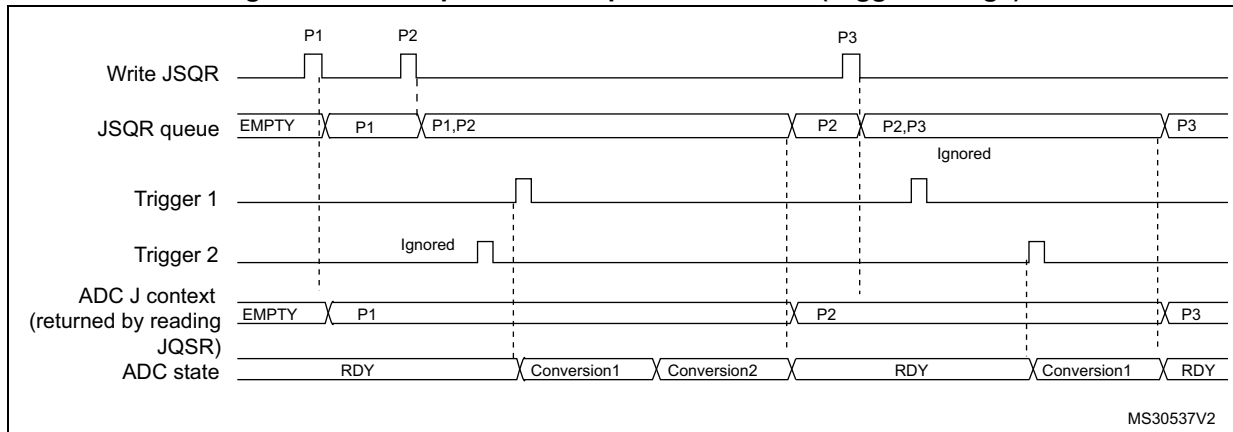

**Figure 138. Example of JSQR queue of context (sequence change)**

1. Parameters:
  - P1: sequence of 3 conversions, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 1
  - P3: sequence of 4 conversions, hardware trigger 1

Figure 139. Example of JSQR queue of context (trigger change)

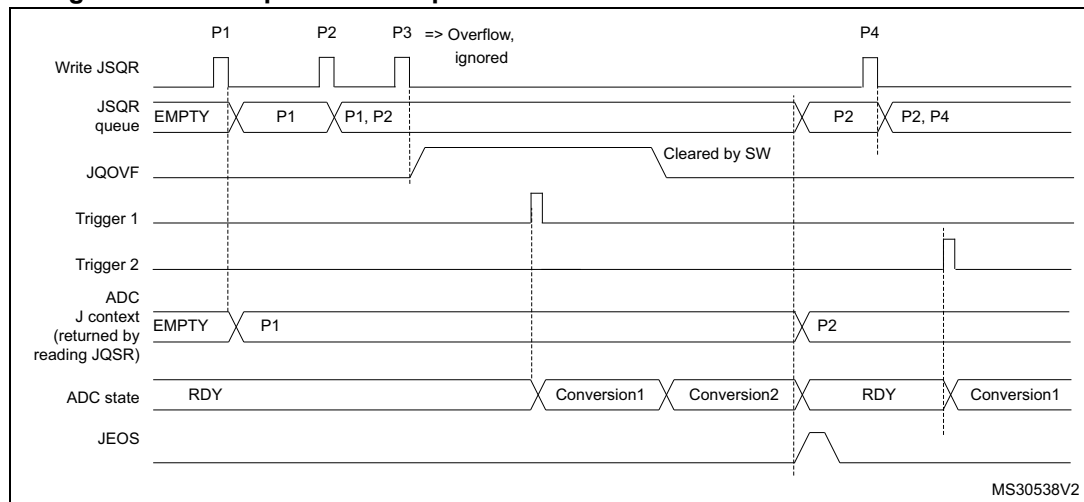

- Parameters:
  - P1: sequence of 2 conversions, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 2
  - P3: sequence of 4 conversions, hardware trigger 1

**Queue of context: Behavior when a queue overflow occurs**

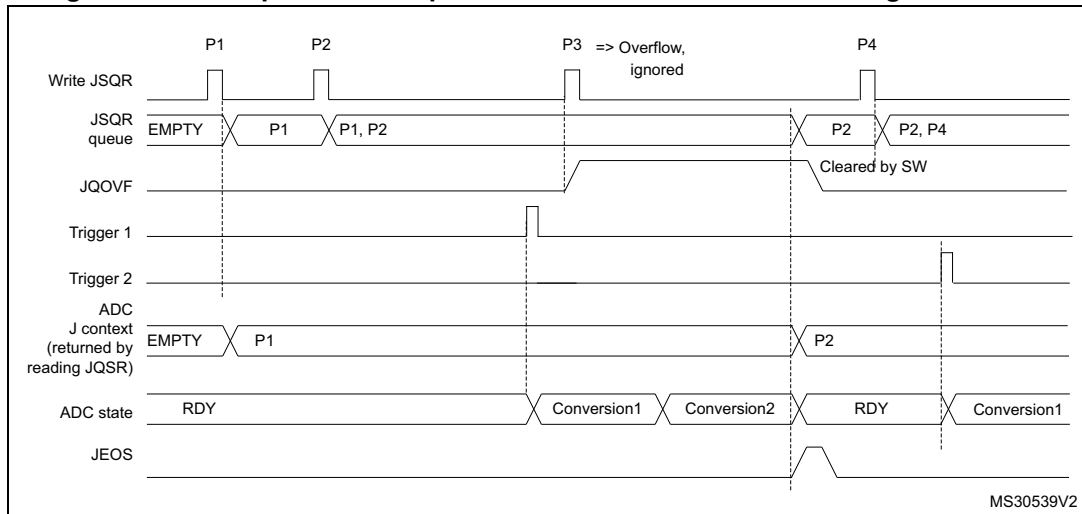

The [Figure 140](#) and [Figure 141](#) show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 140. Example of JSQR queue of context with overflow before conversion

- Parameters:
  - P1: sequence of 2 conversions, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 2
  - P3: sequence of 3 conversions, hardware trigger 1
  - P4: sequence of 4 conversions, hardware trigger 1

Figure 141. Example of JSQR queue of context with overflow during conversion

- Parameters:  
 P1: sequence of 2 conversions, hardware trigger 1  
 P2: sequence of 1 conversion, hardware trigger 2  
 P3: sequence of 3 conversions, hardware trigger 1  
 P4: sequence of 4 conversions, hardware trigger 1

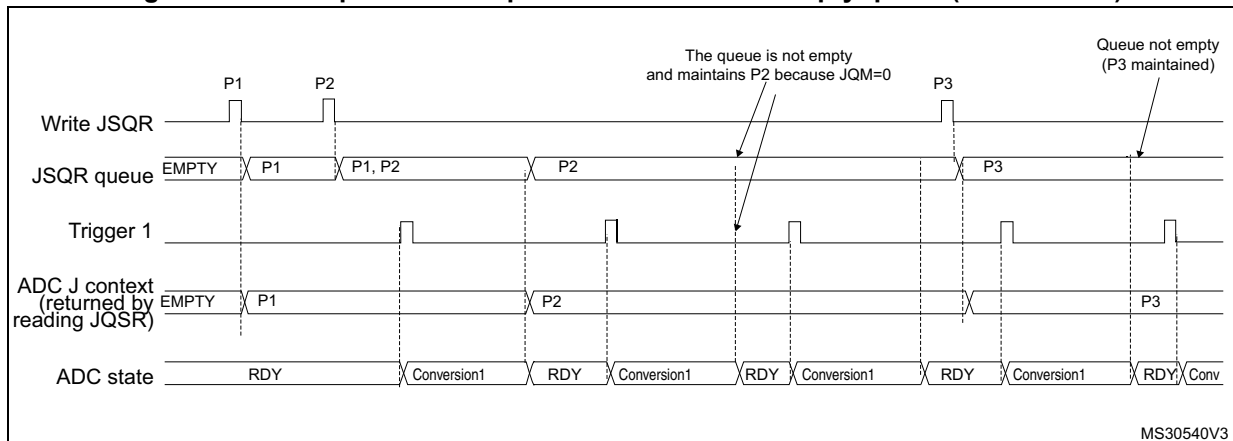

It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

Figure 142 and Figure 143 show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

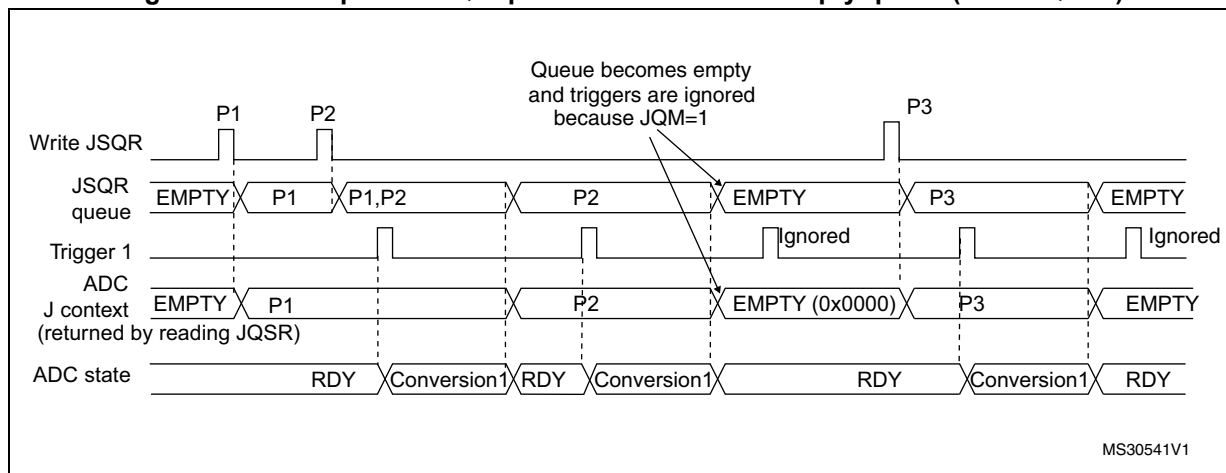

Figure 142. Example of JSQR queue of context with empty queue (case JQM=0)

- Parameters:  
 P1: sequence of 1 conversion, hardware trigger 1  
 P2: sequence of 1 conversion, hardware trigger 1  
 P3: sequence of 1 conversion, hardware trigger 1

*Note:* When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.

**Figure 143. Example of JSQR queue of context with empty queue (case JQM=1)**

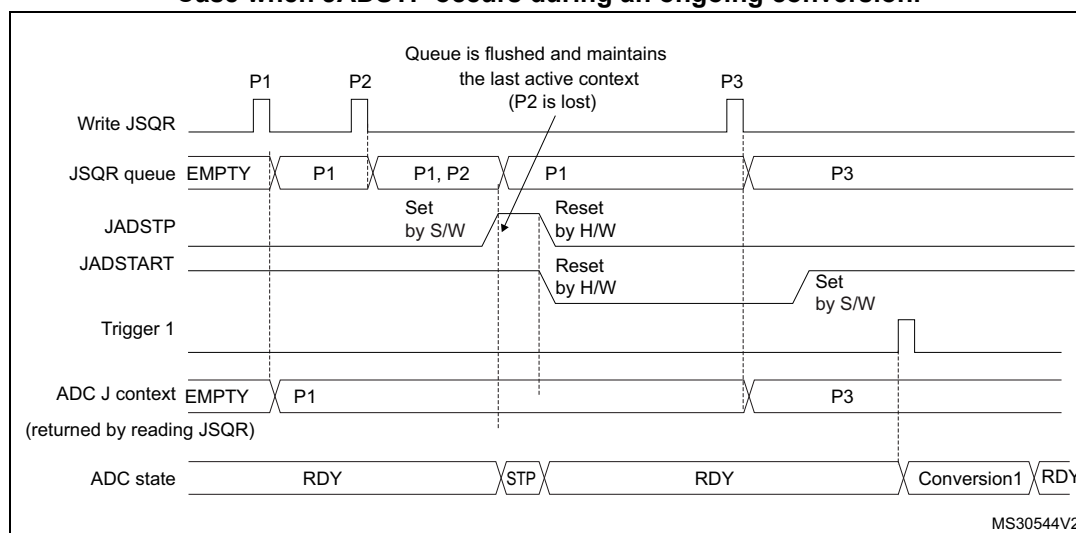

- Parameters:
  - P1: sequence of 1 conversion, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 1
  - P3: sequence of 1 conversion, hardware trigger 1

**Flushing the queue of context**

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

**Figure 144. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion.**

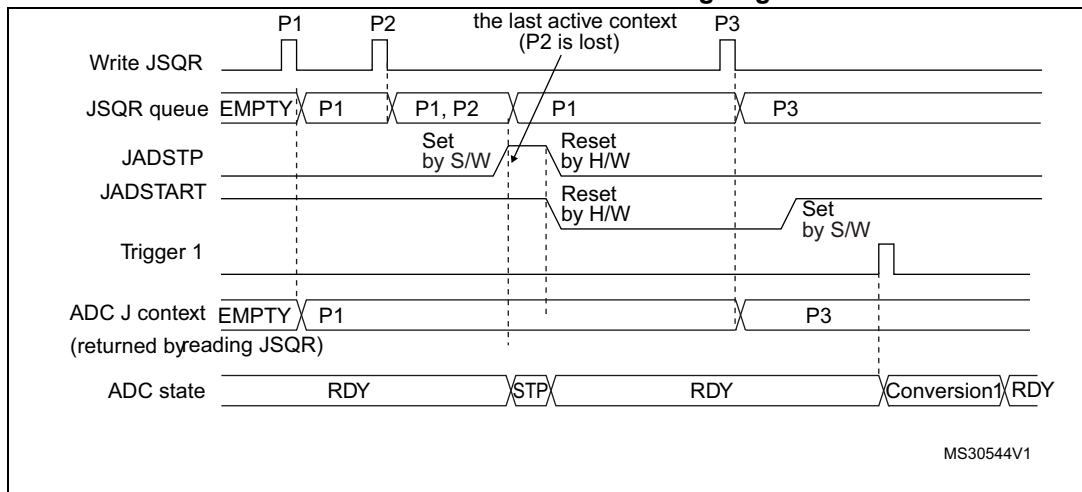

- Parameters:
  - P1: sequence of 1 conversion, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 1
  - P3: sequence of 1 conversion, hardware trigger 1

**Figure 145. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0).  
Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.**

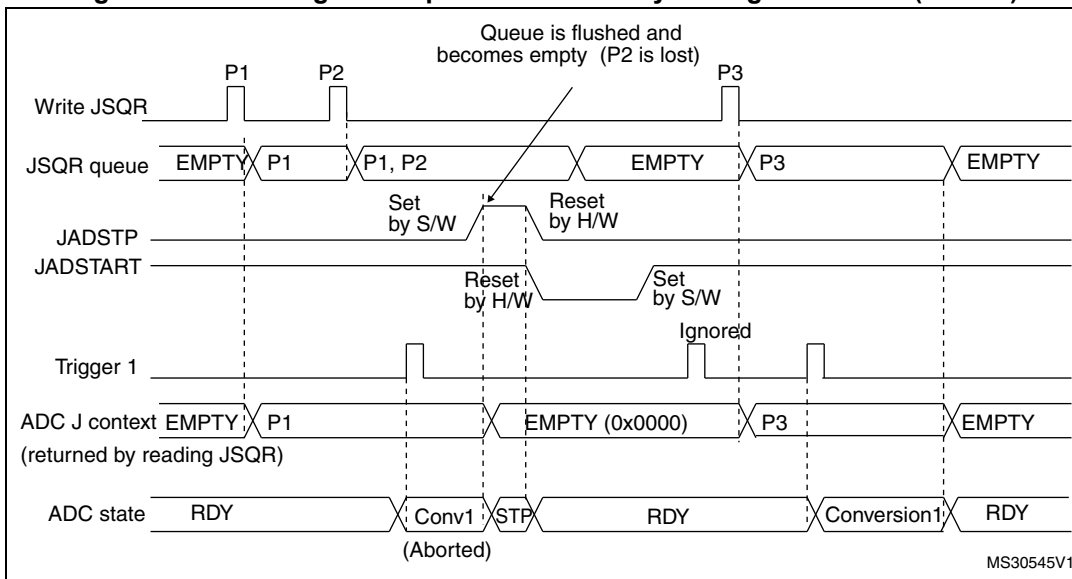

- Parameters:  
 P1: sequence of 1 conversion, hardware trigger 1  
 P2: sequence of 1 conversion, hardware trigger 1  
 P3: sequence of 1 conversion, hardware trigger 1

**Figure 146. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0).  
Case when JADSTP occurs outside an ongoing conversion**

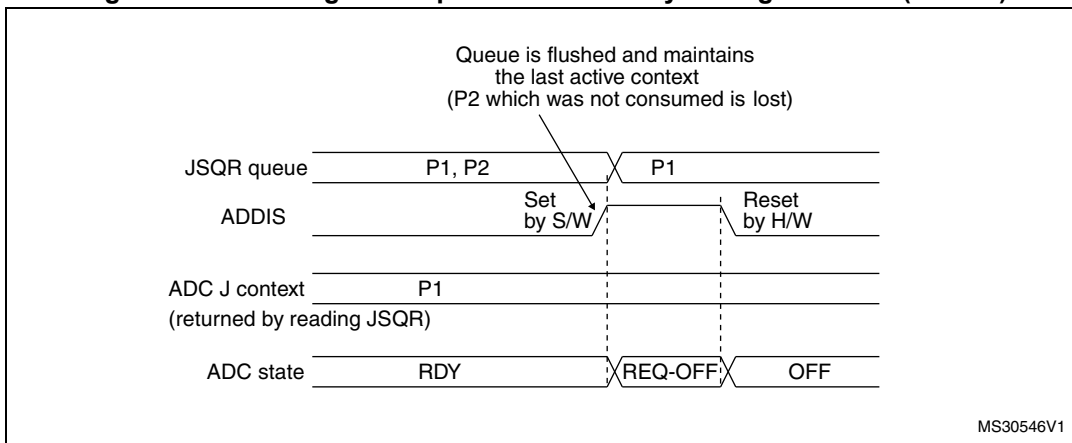

- Parameters:  
 P1: sequence of 1 conversion, hardware trigger 1  
 P2: sequence of 1 conversion, hardware trigger 1  
 P3: sequence of 1 conversion, hardware trigger 1

Figure 147. Flushing JSQR queue of context by setting JADSTP=1 (JQM=1)

- Parameters:
  - P1: sequence of 1 conversion, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 1
  - P3: sequence of 1 conversion, hardware trigger 1

Figure 148. Flushing JSQR queue of context by setting ADDIS=1 (JQM=0)

- Parameters:
  - P1: sequence of 1 conversion, hardware trigger 1
  - P2: sequence of 1 conversion, hardware trigger 1
  - P3: sequence of 1 conversion, hardware trigger 1

**Figure 149. Flushing JSQR queue of context by setting ADDIS=1 (JQM=1)**

1. Parameters:  
 P1: sequence of 1 conversion, hardware trigger 1  
 P2: sequence of 1 conversion, hardware trigger 1  
 P3: sequence of 1 conversion, hardware trigger 1

**Queue of context: Starting the ADC with an empty queue**

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

**Disabling the queue**

It is possible to disable the queue by setting bit JQDIS=1 into the ADCx\_CFGR register.

**Queue of context: Programming of the register ADCx\_JSQR**

When the injected conversion queue of context is enabled (JQDIS=0), the ADCx\_JSQR must be programmed at one register write access. As JL[1:0] register define the number of the injected sequence, corresponding JSQ1 to JSQ4 must be written at same time. If ADCx\_JSQR is reprogrammed before the injected conversion start, reprogrammed data is put on the queue. When queue of context is empty, ADCx\_JSQR read back as 0x0000. Register access should not use the 'read modify write' sequence.

When ADCx\_JSQR is programmed when already 2 contexts are queued, it will raise JQOVF flag and generate the interrupt.

### 25.3.23 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 16, 14, 12, 10, 8 bits by programming the control bits RES[1:0]. [Figure 154](#), [Figure 155](#), [Figure 156](#) and [Figure 157](#) show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to [Table 195](#).

**Table 195. T<sub>SAR</sub> timings depending on resolution**

RES	T <sub>SAR</sub> (ADC clock cycles)	T <sub>SAR</sub> (ns) at F <sub>ADC</sub> =24 MHz	T <sub>ADC</sub> (ADC clock cycles) (with Sampling Time= 1.5 ADC clock cycles)	T <sub>ADC</sub> (ns) at F <sub>ADC</sub> =24 MHz
16	8.5 ADC clock cycles	354.2	10 ADC clock cycles	416.7
14	7.5 ADC clock cycles	312.5	9 ADC clock cycles	375
12	6.5 ADC clock cycles	270.8	8 ADC clock cycles	333.3
10	5.5 ADC clock cycles	229.2	7 ADC clock cycles	291.7
8	4.5 ADC clock cycles	187.5	6 ADC clock cycles	250.0

### 25.3.24 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADCx\_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADCx\_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADCx\_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADCx\_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

### 25.3.25 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADCx\_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

2. Channels selected = 1, 2, 3, 4; AUTDLY=0.

### 25.3.27 Data management

#### Data register, data alignment and offset (ADCx\_DR, ADCx\_JDRy, OFFSETy, OFFSETy\_CH, OVSS, LSHIFT, RSHIFT, SSATE)

##### Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADCx\_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADCx\_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADCx\_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in [Figure 154](#), [Figure 155](#), [Figure 156](#) and [Figure 157](#).

**Note:** The data can be re-aligned in normal and in oversampling mode.

**Offset**

An offset  $y$  ( $y=1,2,3,4$ ) can be applied to a channel by programming a value different from 0 in OFFSETy[25:0] bit field into ADCx\_OFRy register. The channel to which the offset will be applied is programmed into the bits OFFSETy\_CH[4:0] of ADCx\_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[25:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

The offset value should be lower than the max conversion value (ex. 16bit mode, offset value max is 0xFFFF).

The offset correction is also supported in oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 196 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

**Table 196. Offset computation versus data resolution**

Resolution (bits RES[2:0])	Subtraction between raw converted data and offset:		Result	Comments
	Raw converted Data, left aligned	Offset		
000: 16-bit	DATA[15:0]	OFFSET[25:0]	signed 27-bit data	-
001: 14-bit	DATA[15:2],00	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[1:0] to 00
010: 12-bit	DATA[15:4],0000	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[3:0] to 0000
011: 10-bit	DATA[15:6],000000	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[5:0] to 000000
100: 8-bit	DATA[15:8],00000000	OFFSET[25:0]	signed 27-bit data	The user must configure OFFSET[7:0] to 00000000

When reading data from ADCx\_DR (regular channel) or from ADCx\_JDRy (injected channel,  $y=1,2,3,4$ ) corresponding to the channel "i":

- If one of the offsets is enabled (bit OFFSETy\_EN=1) for the corresponding channel, the read data is signed.
- If none of the four offsets is enabled for this channel, the read data is not signed.

Figure 154, Figure 155, Figure 156 and Figure 157 show alignments for signed and unsigned data together with corresponding OVSS and LSHIFT values.

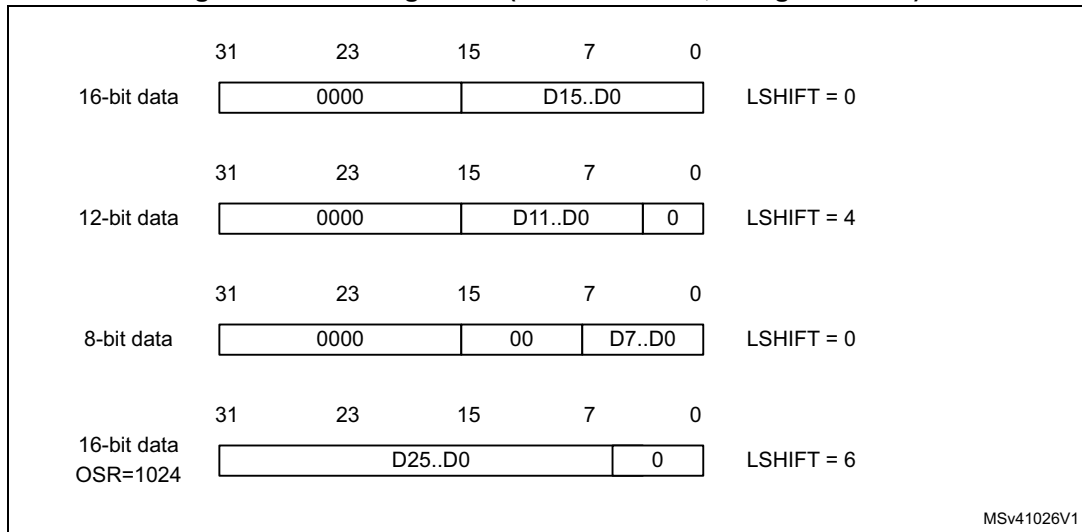

**Figure 154. Right alignment (offset disabled, unsigned value)**

**Figure 155. Right alignment (offset enabled, signed value)**

**Figure 156. Left alignment (offset disabled, unsigned value)**

**Figure 157. Left alignment (offset enabled, signed value)**

**16-bit and 8-bit signed format management: RSHIFTx, SSATE**

The offset correction sign-extends the data format, resulting in an unsigned 16-bit conversion being extended to 17-bit signed format, for instance.

Three options are offered for formatting 8-bit and 16-bit conversion results.

For each offset correction channel 1 to 4, a RSHIFT1..4 bit in the ADCx\_CFGR2 register allows to have the result right-shifted 1-bit and have it fitting a standard 8 or 16-bit format.

Another option is to have the result saturated to the 16-bit and 8-bit signed formats, for the following cases only: RES[2:0] = 000 (16-bit format) and RES[2:0] = 100 (8-bit format).

This mode is enabled with the SSATE bit in the ADCx\_OFRRy register.

The table below summarizes the 3 available use case for 16-bit format.

**Table 197. 16-bit data formats**

SSATE	RSHIFTx	Format	Data range (offset = 0x8000)
0	0	Sign-extended 17-bit significant data SEXT[31:16] DATA[15:0]	0x00007FFF - 0x FFFF8000
0	1	Sign-extended right-shifted 16-bit significant data SEXT[31:15] DATA[14:0]	0x3FFF - 0xC000
1	0	Sign-extended saturated 16-bit significant data SEXT[31:15] DATA[14:0]	7FFF - 0x8000
1	1	Reserved	-

Numerical examples are given in [Table 198](#) with 3 different offset values.

**Table 198. Numerical examples for 16-bit format (bold indicates saturation)**

Raw conversion result	Offset value	Result SSATE = 0 RSHIFT = 0	Result SSATE = 0 RSHIFT = 1	Result SSATE = 1 RSHIFT = 0
0xFFFF	0x8000	0x0000 7FFF	3FFF	7FFF
0x8000		0x0000 0000	0	0
0x0000		0xFFFF 8000	C000	8000
0xFFFF	0x8020	0x0000 7FDF	3FEF	7FDF
0x8000		0xFFFF FFE0	FFF0	FFE0
0x0000		0xFFFF 7FE0	BFF0	8000
0xFFFF	0x7FF0	0x0000 800F	4007	7FFF
0x8000		0x0000 0010	8	0010
0x0000		0xFFFF 8010	C008	8010

When oversampling mode is active, the SSATE and RSHIFT1..4 bits are not supported.

**ADC overrun (OVR, OVRMOD)**

The overrun flag (OVR) notifies of a buffer overrun event, when the regular converted data was not read (by the CPU or the DMA) before new converted data became available.

The OVR flag is set if the EOC flag is still 1 at the time when a new conversion completes. An interrupt can be generated if bit OVRIE=1.

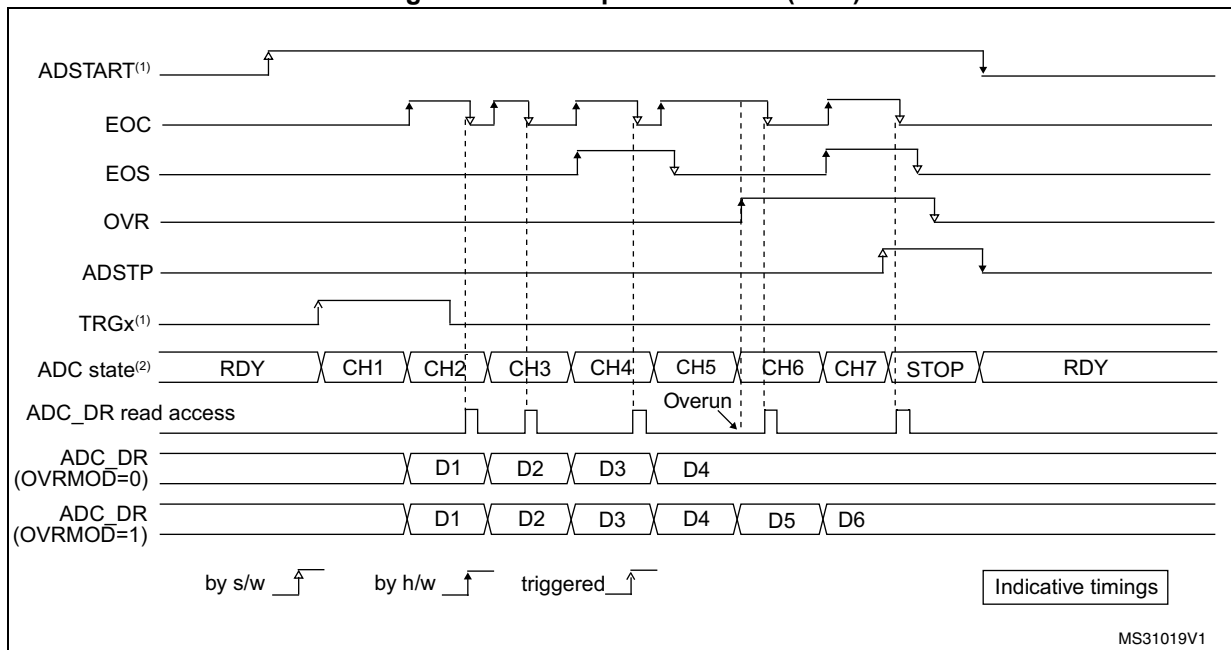

When an overrun condition occurs, the ADC is still operating and can continue to convert unless the software decides to stop and reset the sequence by setting bit ADSTP=1.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD=0: The overrun event preserves the data register from being overrun: the old data is maintained and the new conversion is discarded and lost. If OVR remains at 1, any further conversions will occur but the result data will be also discarded.
- OVRMOD=1: The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, any further conversions will operate normally and the ADCx\_DR register will always contain the latest converted data.

**Figure 158. Example of overrun (OVR)**

MS31019V1

*Note:* There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

**Managing a sequence of conversion without using the DMA**

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADCx\_DR register can be read. OVRMOD should be configured to 0 to manage overrun events as an error.

### Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event will not prevent the ADC from continuing to convert and the ADCx\_DR register will always contain the latest conversion.

### Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADCx\_DR register.

When the DMA mode is enabled (DMNGT bit = 01 or 11 in the ADCx\_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADCx\_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to [Section : ADC overrun \(OVR, OVRMOD\)](#)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMNGT of the ADCx\_CFGR register in single ADC mode, or with bit DAMDF of the ADCx\_CCR register in dual ADC mode:

- DMA one shot mode (DMNGT bit = 01).  
This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT bit = 11)  
This mode is suitable when programming the DMA in circular mode.

#### DMA one shot mode (DMNGT=01)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA\_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

### DMA circular mode (DMNGT=11)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

### DMA with FIFO

The output data register has 8 stage FIFO. Two different DMA requests are generated parallel. When a data is available, "SREQ single request" generated, when 4 data are available, "BREQ burst request" generated. DMA2 can be programmed either single transfer mode or incremental burst mode(4 beats), according to this mode, correct request line is selected by the DMA2. Please refer to the DMA2 chapter for further information.

## 25.3.28 Managing conversions using the DFSDM

The ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

In this case, the DMNGT[1:0] bits must be set to 10.

The ADC transfers 16 least significant bits of the regular data register data to the DFSDM, which in turns will reset the EOC flag once the transfer is effective.

The data format must be 16-bit signed:

ADCx\_DR[31:16] = don't care

ADCx\_DR[15] = sign

ADCx\_DR[14:0] = data

Any value above 16-bit signed format will be truncated.

## 25.3.29 Dynamic low-power features

### Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADCx\_DR register has been read or if the EOC bit has been cleared (see [Figure 159](#)).
- For an injected conversion: when the JEOS bit has been cleared (see [Figure 160](#)).

This is a way to automatically adapt the speed of the ADC to the speed of the system which will read the data.

The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

*Note:* There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

*Note:* This is not true for software triggers where it remains possible during this delay to set the bits *ADSTART* or *JADSTART* to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see [Figure 160](#)).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see [Figure 162](#)).

The behavior is slightly different in auto-injected mode (*JAUTO*=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when *JEOS* has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see [Figure 163](#)).

To stop a conversion in continuous auto-injection mode combined with autodelay mode (*JAUTO*=1, *CONT*=1 and *AUTDLY*=1), follow the following procedure:

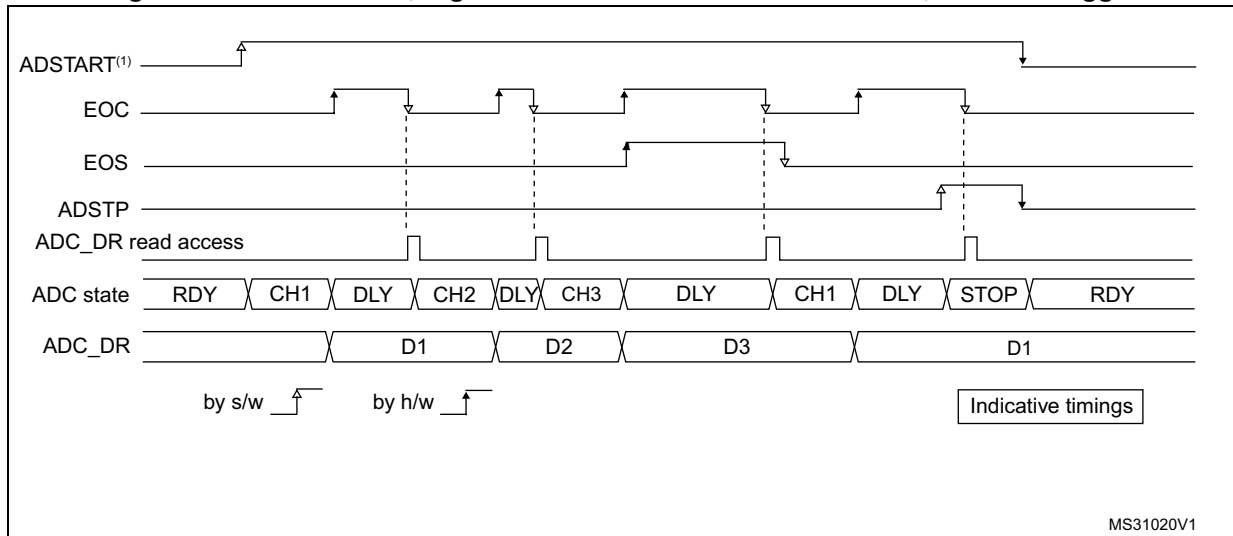

1. Wait until *JEOS*=1 (no more conversions are restarted)
2. Clear *JEOS*,
3. Set *ADSTP*=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if *JEOS* is cleared after *ADSTP* has been set.

In *AUTDLY* mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

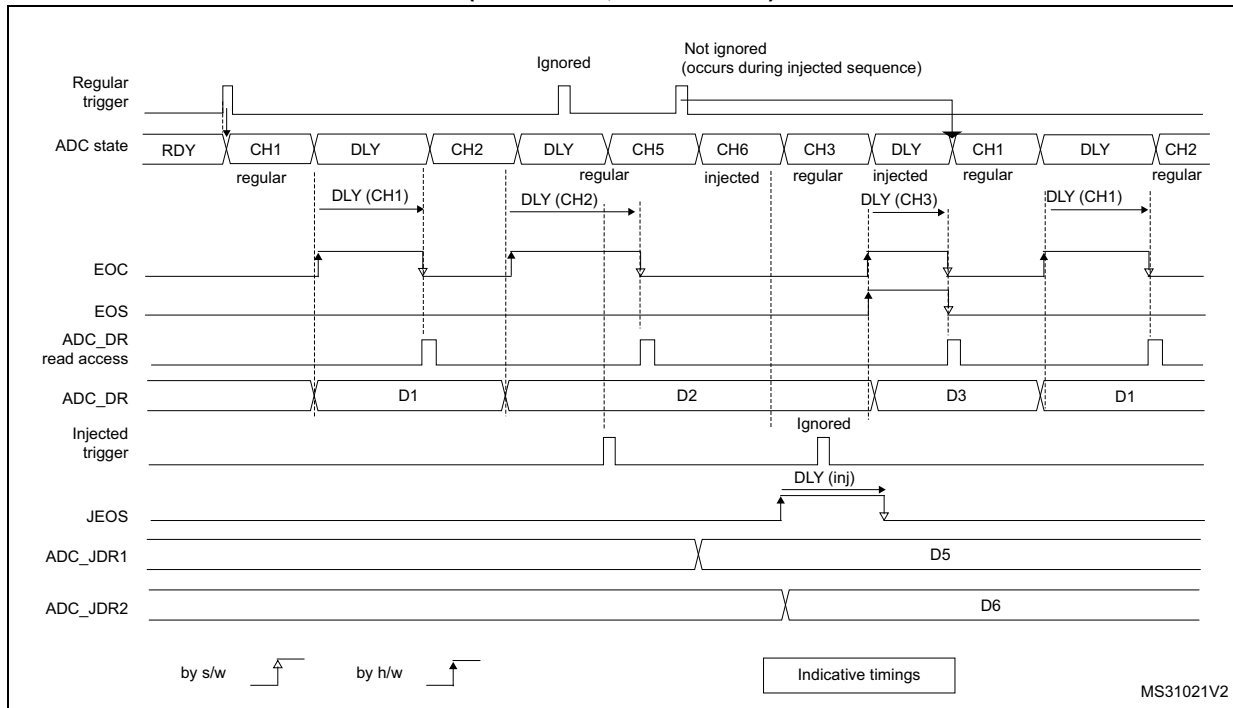

In *AUTDLY* mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

### 25.3.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\_HTRy, AWD\_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 164. Analog watchdog's guarded area**

#### AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADCx\_IER register (x=1,2,3).

AWDy (y=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

#### Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADCx\_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels<sup>(1)</sup> remain within a configured voltage range (window).

Table 199 shows how the ADCx\_CFGRy registers should be configured to enable the analog watchdog on one or more channels.

**Table 199. Analog watchdog channel selection**

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single <sup>(1)</sup> injected channel	1	0	1
Single <sup>(1)</sup> regular channel	1	1	0
Single <sup>(1)</sup> regular or injected channel	1	1	1

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed in bits HTR1[25:0] of the ADCx\_HTR1 register and LTR1[25:0] of the ADCx\_LTR1 register for the analog watchdog 1.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSR=1024).

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

Table 200 describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

**Table 200. Analog watchdog 1,2,3 comparison**

Resolution (bit RES[2:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned <sup>(1)</sup>	Thresholds	
000: 16-bit	DATA[15:0]	LTR1[25:0] and HTR1[25:0]	-
001: 14-bit	DATA[15:2],00	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[1:0] and HTR1[1:0] to 00
010: 12-bit	DATA[15:4],0000	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[3:0] and HTR1[3:0] to 0000
011: 10-bit	DATA[15:6],00000 0	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[5:0] and HTR1[5:0] to 000000
100: 8-bit	DATA[15:8],00000 000	LTR1[25:0] and HTR1[25:0]	User must configure LTR1[7:0] and HTR1[7:0] to 00000000

1. The watchdog comparison is performed on the raw converted data before any alignment calculation and before applying any offsets (the data which is compared is not signed).

**Description of analog watchdog 2 and 3**

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHy[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHy[19:0] (y=2,3) is set.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSR=1024) and are programmed with the ADCx\_HTR2, ADCx\_LTR2, ADCx\_LTR3, and ADCx\_HTR3 registers.

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

**ADCx\_AWDy\_OUT signal output generation**

Each analog watchdog is associated to an internal hardware signal ADCx\_AWDy\_OUT (x=ADC number, y=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCx\_AWDy\_OUT signal as ETR.

ADCx\_AWDy\_OUT is activated when the associated analog watchdog is enabled:

- ADCx\_AWDy\_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCx\_AWDy\_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCx\_AWDy\_OUT is also reset when disabling the ADC (when setting ADDIS=1). Note that stopping regular or injected conversions (setting ADSTP=1 or JADSTP=1) has no influence on the generation of ADCy\_AWDx\_OUT.

*Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADCx\_AWDy\_OUT (ex: ADCy\_AWDy\_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).*

**Figure 165. ADCy\_AWDx\_OUT signal generation (on all regular channels)**

**Figure 166. ADCy\_AWDx\_OUT signal generation (AWDx flag not cleared by SW)**

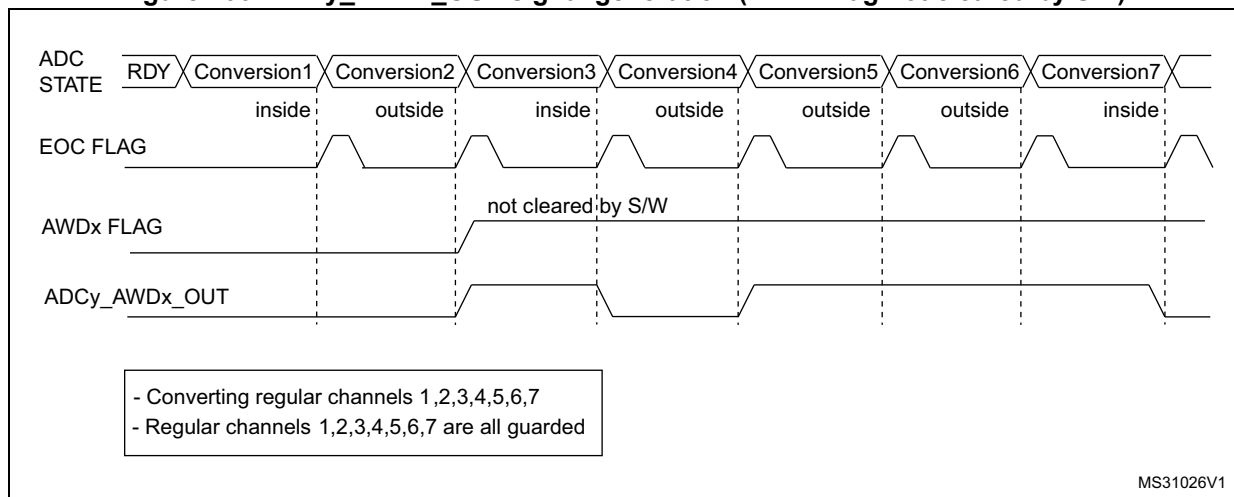

Figure 167. ADCy\_AWDx\_OUT signal generation (on a single regular channel)

Figure 168. ADCy\_AWDx\_OUT signal generation (on all injected channels)

### 25.3.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 26-bit (16-bit values and OSR = 1024).

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

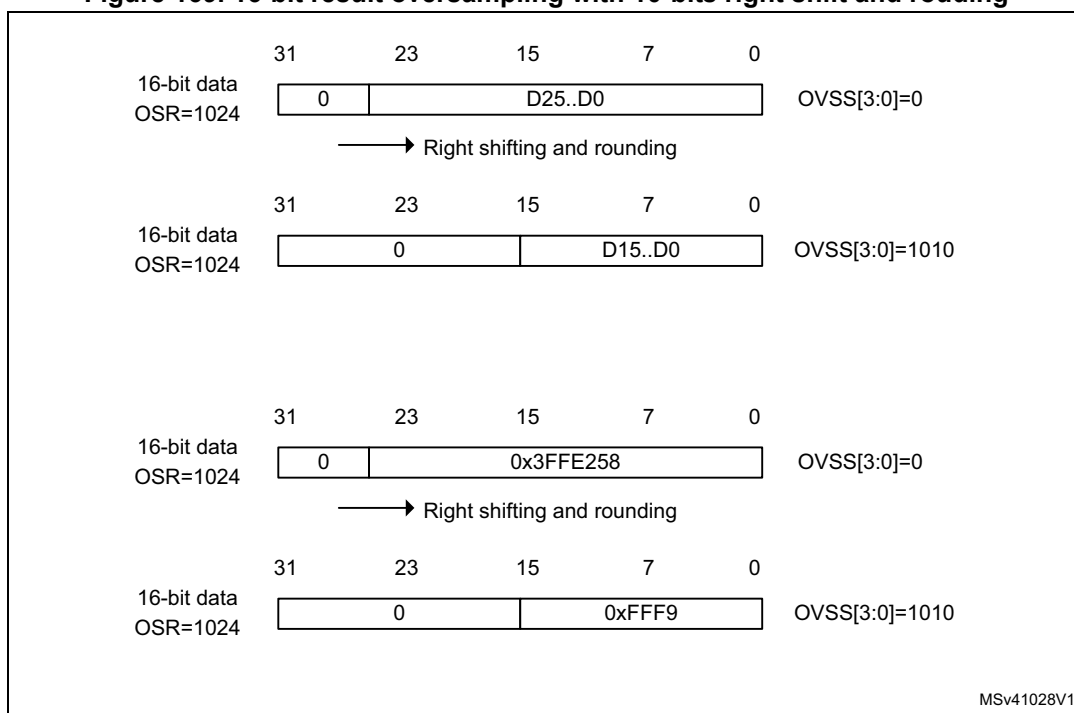

The oversampling ratio N is defined using the OSR[9:0] bits in the ADCx\_CFGR2 register, and can range from 2x to 1024x. The division coefficient M consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADCx\_CFGR2 register.

The summation unit can yield a result up to 26 bits (1024 x 16-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADCx\_DR data register.

The [Table 169](#) gives a numerical example of the processing, from a raw 26-bit accumulated data to the final 16-bit result.

**Figure 169. 16-bit result oversampling with 10-bits right shift and rounding**

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversions, with an equivalent delay equal to  $N \times T_{CONV} = N \times (t_{SMPL} + t_{SAR})$ . The flags are set as follow:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- the end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total)

### Single ADC operating modes support when oversampling

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[2:0] bits in ADCx\_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 16-bit conversions are

*Note:* The alignment mode is not available when working with oversampled data. The ALIGN bit in ADCx\_CFGR is ignored and the data are always provided right-aligned.

*Note:* Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy\_EN bit in ADCx\_OFRRy register is ignored (considered as reset).

### Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- the RES[2:0] bits are ignored, comparison is always done on using the full 12-bit values HT[11:0] and LT[11:0]
- the comparison is performed on the most significant 12-bit of the 16-bit oversampled results ADCx\_DR[15:4]

*Note:* Care must be taken when using high shifting values, this will reduce the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADCx\_DR[11:4] and HT[0:7] / LT[[0:7], and HT[11:8] / LT[11:8] must be kept reset.

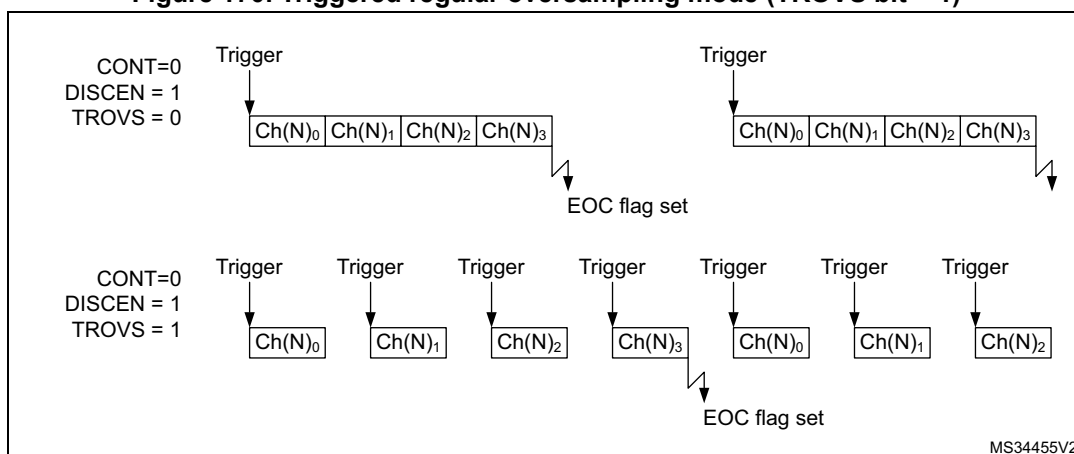

### Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADCx\_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The [Figure 170](#) below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 170. Triggered regular oversampling mode (TROVS bit = 1)

### Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

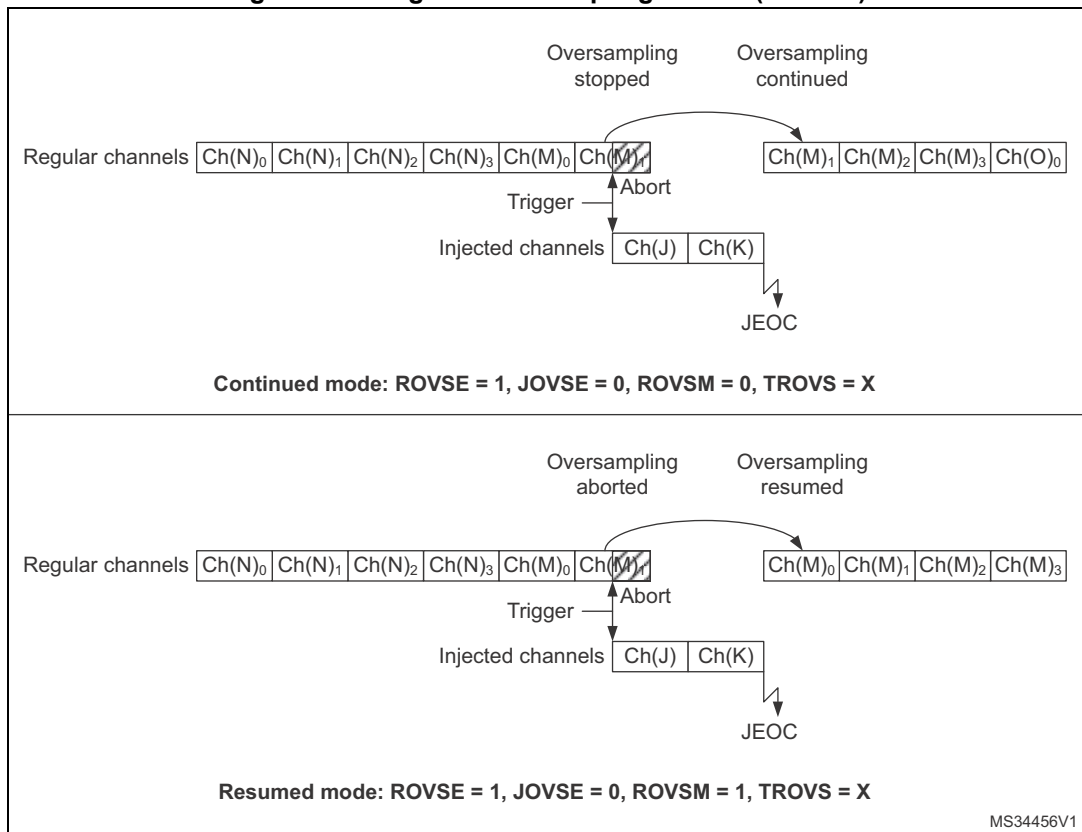

### Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- in continued mode, the accumulation re-starts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling will be completed whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- in resumed mode, the accumulation re-starts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer will be blocked.

The [Figure 171](#) gives examples for a 4x oversampling ratio.

**Figure 171. Regular oversampling modes (4x ratio)**

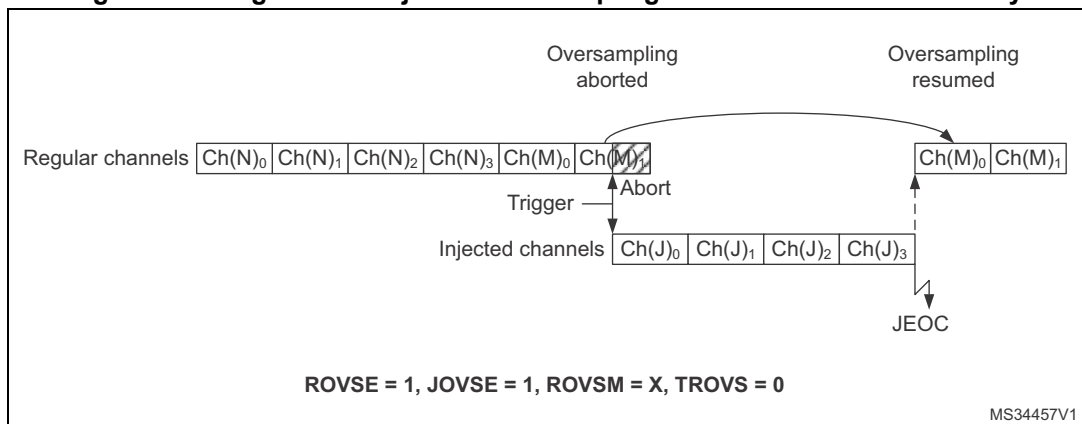

**Oversampling Injected channels only**

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

**Oversampling regular and injected channels**

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on [Figure 172](#) below.

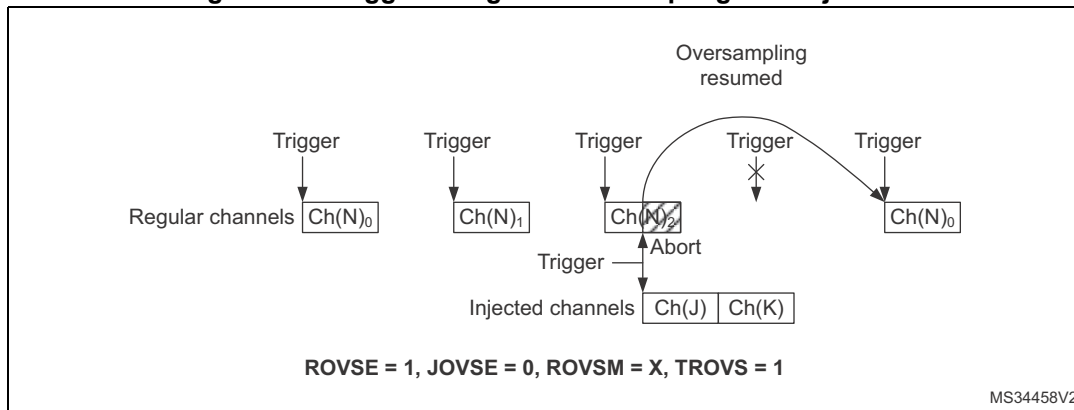

**Figure 172. Regular and injected oversampling modes used simultaneously**

**Triggered regular oversampling with injected conversions**

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVS<sub>M</sub> bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on [Figure 173](#) below.

**Figure 173. Triggered regular oversampling with injection**

**Autoinjected mode**

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The [Figure 174](#) below shows how the conversions are sequenced.

**Figure 174. Oversampling in auto-injected mode**

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO=1, DISCEN=0, JDISCEN=0, ROVSE=1, JOVSE=1 and TROVSE=1.

**Dual ADC modes support when oversampling**

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

**Combined modes summary**

The [Table 201](#) below summarizes all combinations, including modes not supported.

**Table 201. Oversampler operating modes summary**

Regular Over-sampling ROVSE	Injected Over-sampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered Regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

**25.3.32 Dual ADC modes**

In devices with two ADCs or more, dual ADC modes can be used (see [Figure 175](#)):

- ADC1 and ADC2 can be used together in dual mode (ADC1 is master)

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx\_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx\_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADCx\_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger,

and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don't care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx\_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx\_CSR).

Figure 175. Dual ADC block diagram<sup>(1)</sup>

1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCx\_CDR) contains both the master and slave ADC regular converted data.

### Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL[4:0] bits in the ADCx\_JSQR register).

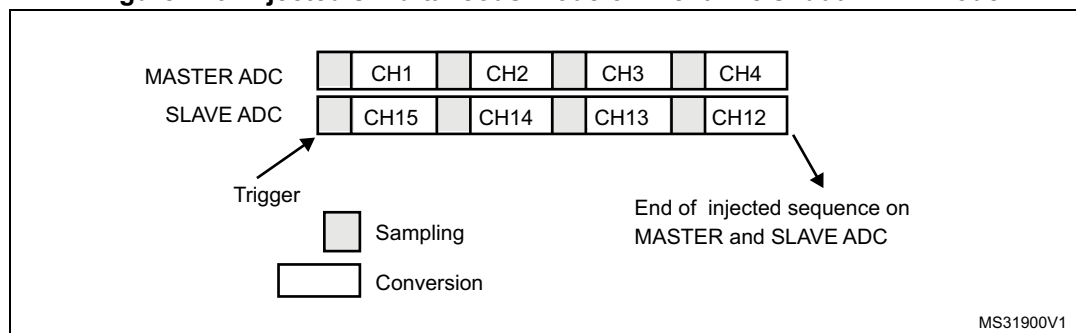

*Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).*

*In simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time.*

*Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.*

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADCx\_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADCx\_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in [Figure 176](#)), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADCx\_JDRy and slave ADCx\_JDRy registers).

**Figure 176. Injected simultaneous mode on 4 channels: dual ADC mode**

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADCx\_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.

### Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL[4:0] bits in the ADCx\_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) will abort the current simultaneous conversions, which are re-started once the injected conversion is completed.

*Note:* Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

*In regular simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master and slave must be configured with the same sampling time.*

Software is notified by interrupts when it can read the data:

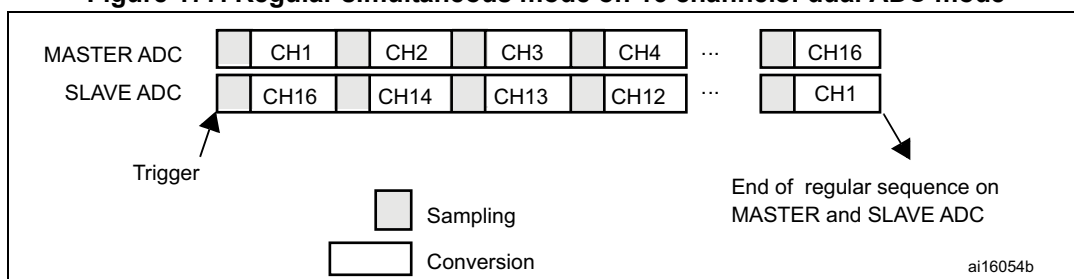

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADCx\_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADCx\_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in [Figure 177](#)), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx\_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits DAMDF[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADCx\_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADCx\_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configuring Dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  - Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx\_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx\_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx\_CDR register.
  - both EOC flags are cleared when the DMA reads the ADCx\_CDR register.

*Note:* When DAMDF[1:0]=0b10 or 0b11, the user must program the same number of conversions in the master's sequence as in the slave's sequence. Otherwise, the remaining conversions will not generate a DMA request.

**Figure 177. Regular simultaneous mode on 16 channels: dual ADC mode**

If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx\_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx\_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

*Note:* This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADCx\_CCR register. This delay starts to count after the end of the sampling phase of the master conversion. This way, an ADC cannot start a conversion if the

complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

Software is notified by interrupts when it can read the data:

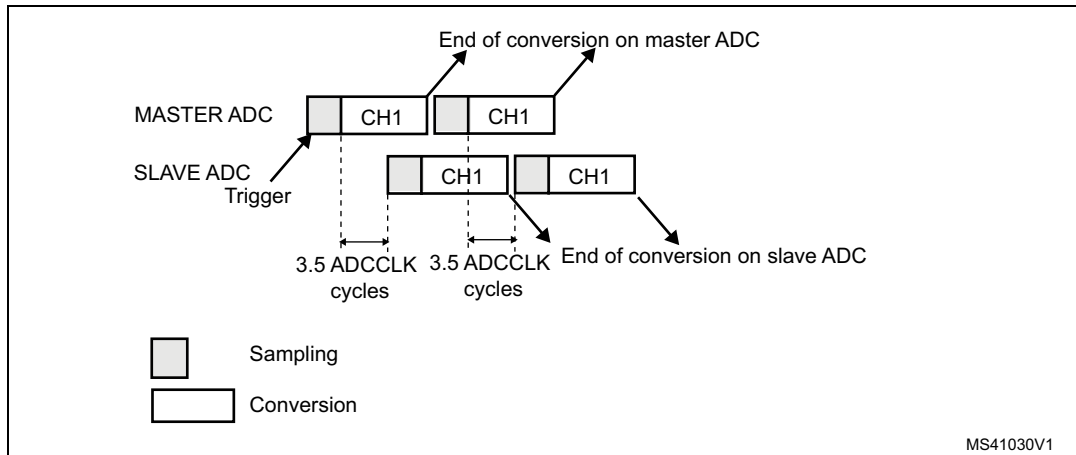

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADCx\_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADCx\_DR of the slave ADC.

*Note: It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx\_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts.*

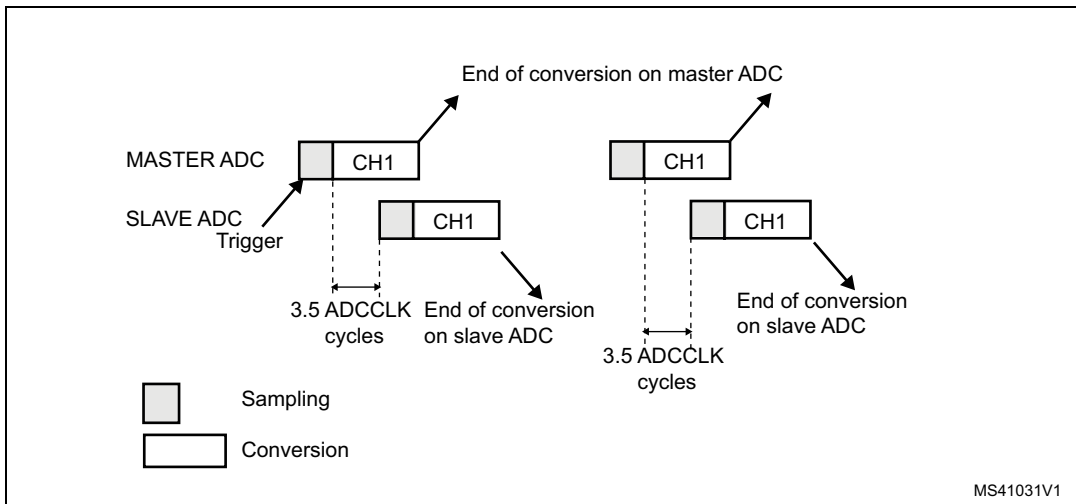

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx\_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx\_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx\_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx\_CCR register.

**Figure 178. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode**

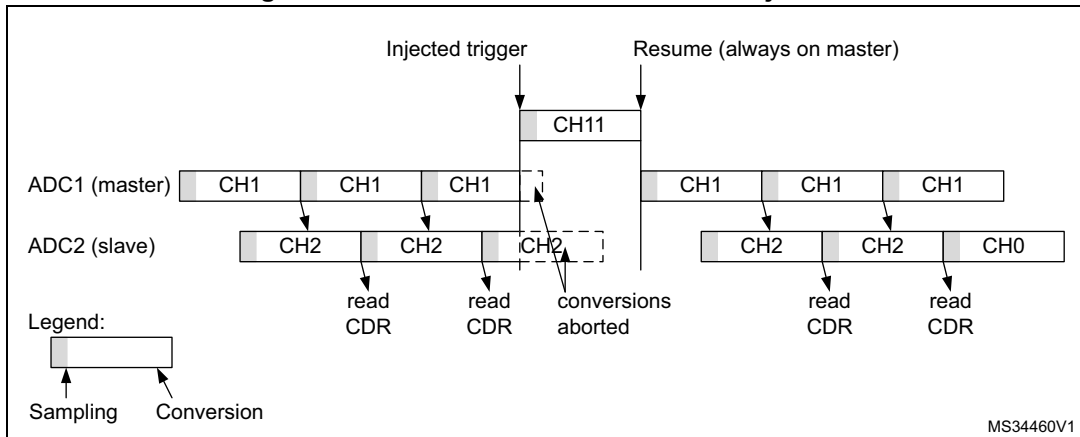

**Figure 179. Interleaved mode on 1 channel in single conversion mode: dual ADC mode**

If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is re-started from the master (see [Figure 180](#) below).

Figure 180. Interleaved conversion with injection

MS34460V1

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.

**Injected discontinuous mode disabled (JDISCEN=0 for both ADC)**

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

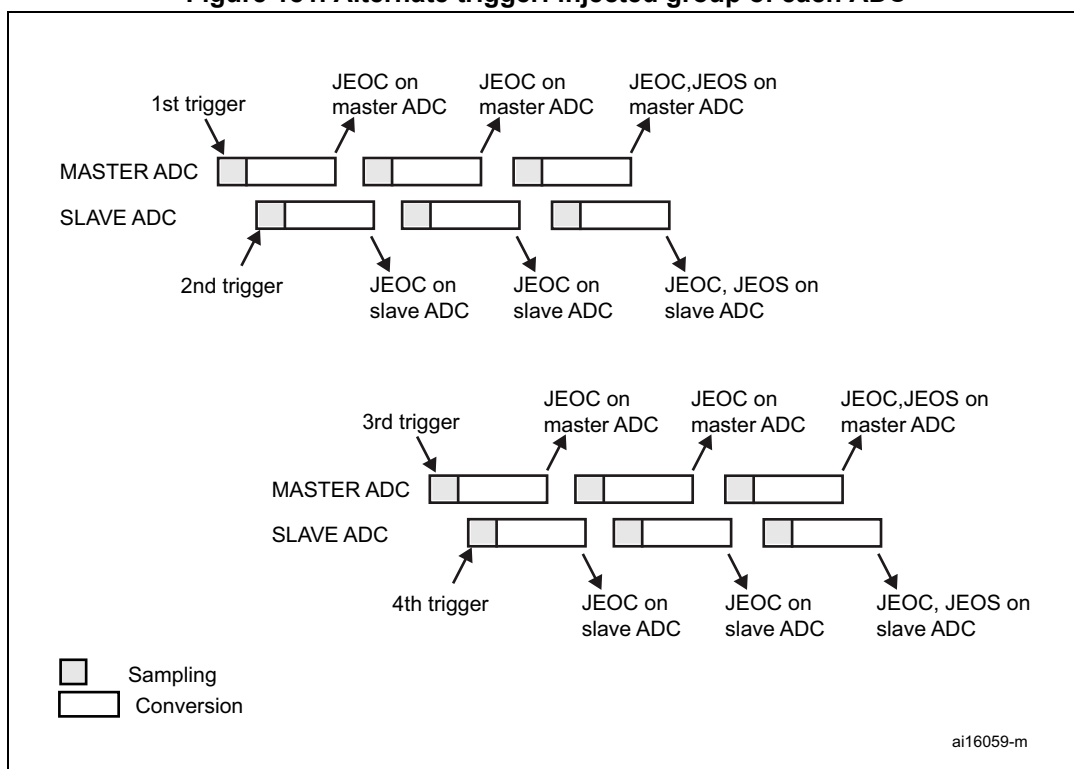

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 181. Alternate trigger: injected group of each ADC

**Note:** Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

**Injected discontinuous mode enabled (JDISCEN=1 for both ADC)**

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

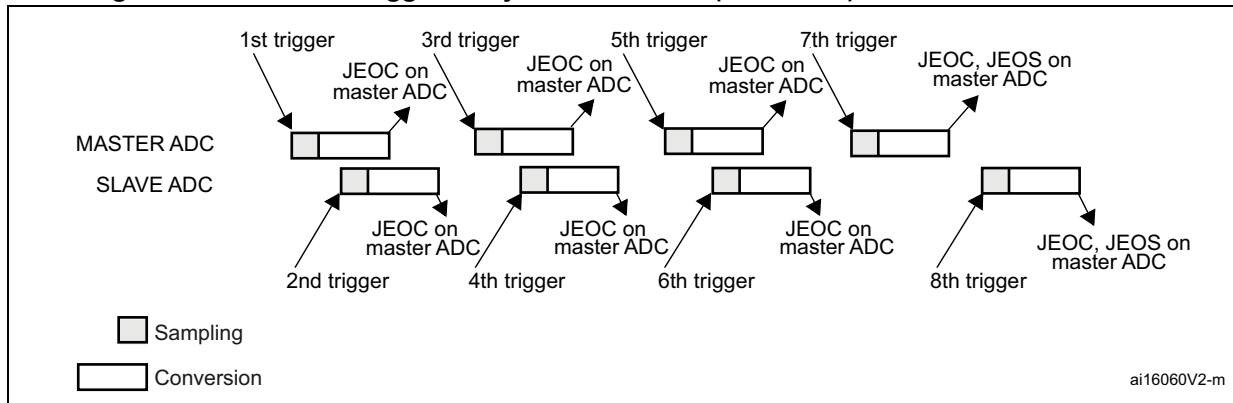

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 182. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

**Combined regular/injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Combined regular simultaneous + alternate trigger mode**

This mode is selected by programming bits DUAL[4:0]=00010.

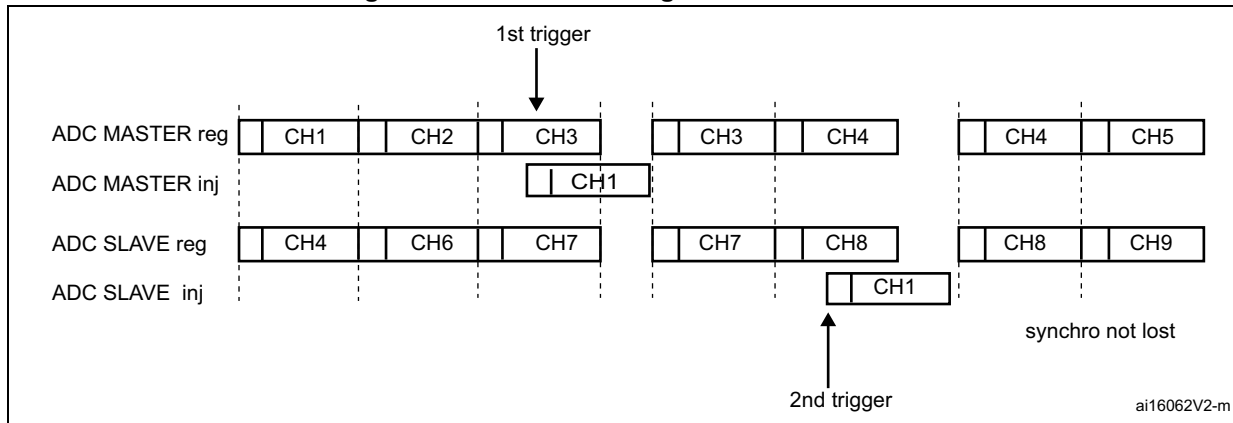

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. [Figure 183](#) shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

*Note:* The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

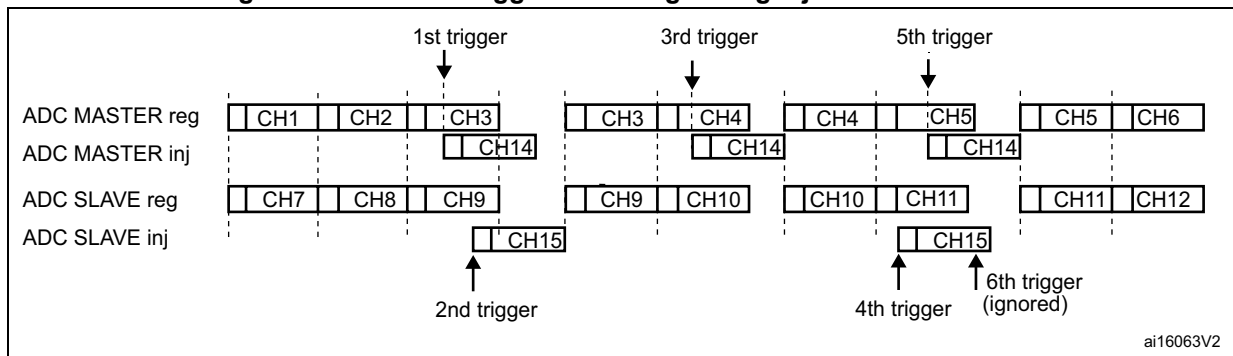

Figure 183. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. [Figure 184](#) shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

Figure 184. Case of trigger occurring during injected conversion

### Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0]=00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master's one. [Figure 185](#), [Figure 186](#) and [Figure 187](#) show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.

**Figure 185. Interleaved single channel CH0 with injected sequence CH11, CH12**

**Figure 186. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 1: Master interrupted first**

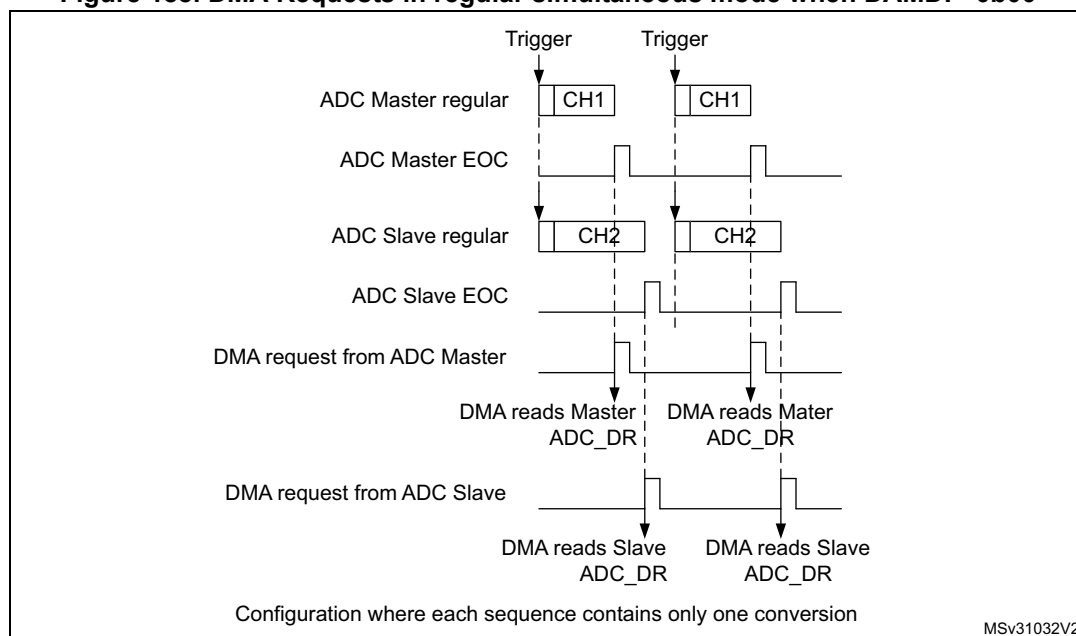

**Figure 187. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12 - case 2: Slave interrupted first**

### DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to [Figure 188: DMA Requests in regular simultaneous mode when DAMDF=0b00](#)).

**Figure 188. DMA Requests in regular simultaneous mode when DAMDF=0b00**

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this DAMDF bits must be configured in the ADCx\_CCR register:

- DAMDF=0b10, 32-bit format:** A single DMA request is generated alternatively when either the master or slave EOC events have occurred. At that time, the data items are alternatively available in the ADCx\_CDR2 32-bit register. This mode is used in interleaved mode and in regular simultaneous mode when resolution is above 16-bit.

**Example:**

Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:

1st DMA request: ADCx\_CDR2[31:0] = MST\_ADC\_DR[31:0]

2nd DMA request: ADCx\_CDR2[31:0] = SLV\_ADC\_DR[31:0]
- DAMDF=0b10, 16-bit format:** A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx\_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

This mode is used in interleaved mode and in regular simultaneous mode when

resolution is ranging from 10 to 16-bit. Any value above 16-bit in the master or the slave converter will be truncated to the least 16 significant bits.

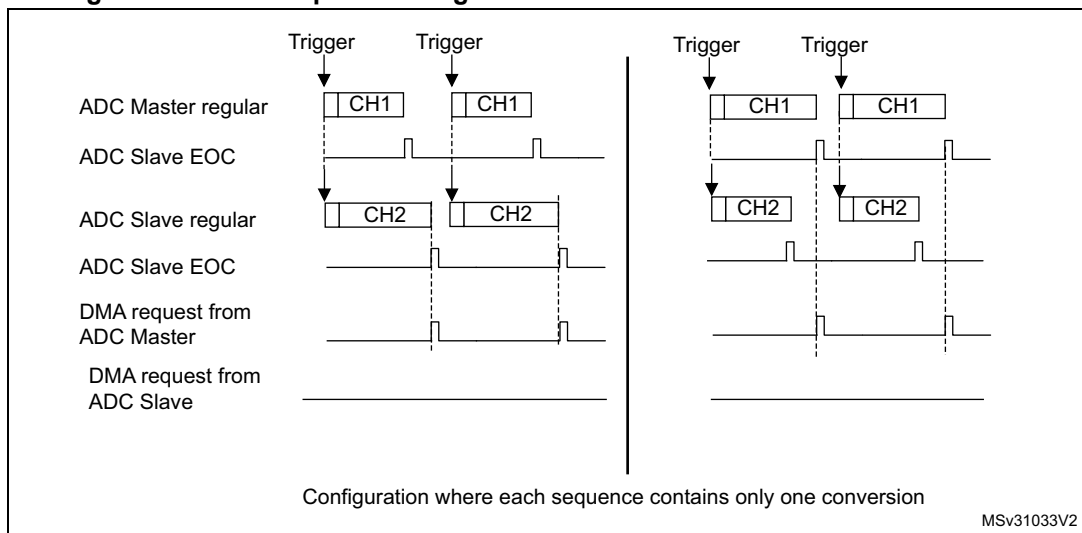

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

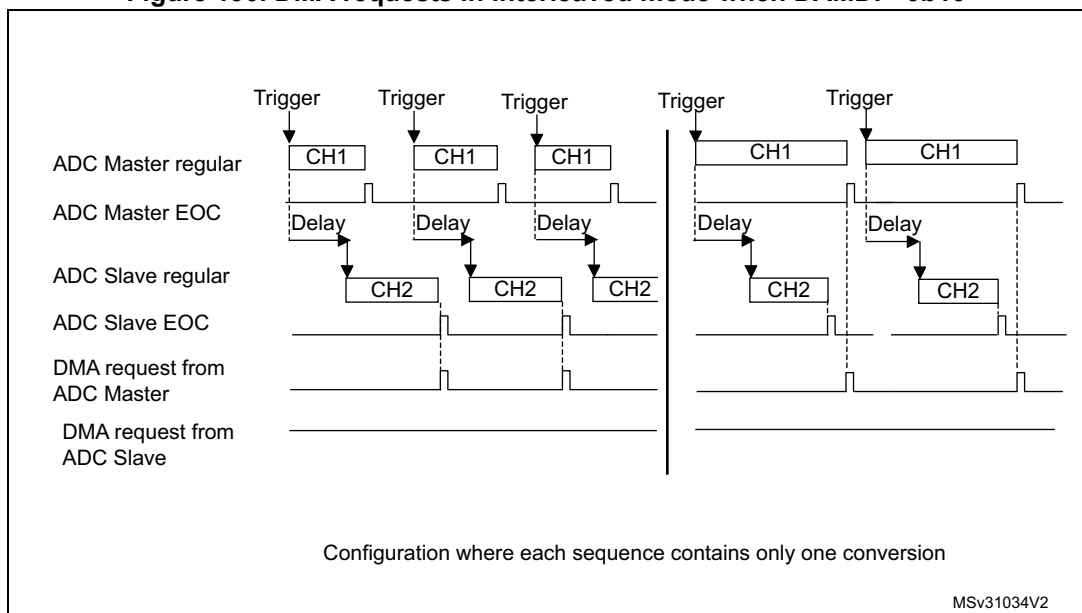

1st DMA request: ADCx\_CDR[31:0] = SLV\_ADCx\_DR[15:0] | MST\_ADCx\_DR[15:0]

2nd DMA request: ADCx\_CDR[31:0] = SLV\_ADCx\_DR[15:0] | MST\_ADCx\_DR[15:0]

**Figure 189. DMA requests in regular simultaneous mode when DAMDF=0b10**

**Figure 190. DMA requests in interleaved mode when DAMDF=0b10**

*Note:* When using Multi ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **DAMDF=0b11:** This mode is similar to the DAMDF=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.

This mode is used in interleaved and regular simultaneous mode when the result is 8-bit. A new DMA request is issued when 4 new 8-bit values are available.

**Example:**

Interleaved dual mode: a DMA request is generated each time 4 data items are available (t0, t1,... are corresponding to the consecutive sampling instants)

1st DMA request:

ADCx\_CDR[7:0] = MST\_ADC\_DR[7:0]<sub>t0</sub>

ADCx\_CDR[15:8] = SLV\_ADC\_DR[7:0]<sub>t0</sub>

ADCx\_CDR[23:16] = MST\_ADC\_DR[7:0]<sub>t1</sub>

ADCx\_CDR[31:24] = SLV\_ADC\_DR[7:0]<sub>t1</sub>

2nd DMA request:

ADCx\_CDR[7:0] = MST\_ADC\_DR[7:0]<sub>t2</sub>

ADCx\_CDR[15:8] = SLV\_ADC\_DR[7:0]<sub>t2</sub>

ADCx\_CDR[23:16] = MST\_ADC\_DR[7:0]<sub>t3</sub>

ADCx\_CDR[31:24] = SLV\_ADC\_DR[7:0]<sub>t3</sub>

### Overrun detection

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

### DMA one shot mode/ DMA circular mode when Multi ADC mode is selected

When DAMDF mode is selected (0b10 or 0b11), bit DMNGT[1:0]=0b10 in the master ADC's ADCx\_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section [Section : Managing conversions using the DMA](#).

### Stopping the conversions in dual ADC modes

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

### DFSDM mode in dual ADC mode interleaved mode

In dual ADC interleaved modes, the ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).

This mode is enabled by setting the bits DMNGT[1:0] = 0b10 in the master ADC's ADCx\_CFGR register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the DFSDM.

The data format must be 16-bit signed:

ADCx\_DR[31:16] = 0x0000

ADCx\_DR[15] = sign

ADCx\_DR[14:0] = data

Any value above 16-bit signed format in any converter will be truncated.

**DFSDM mode in dual ADC simultaneous mode**

The dual mode is not required to use DFSDM in dual ADC simultaneous mode since conversion data will be treated by each individual channel. Single mode with same trigger source results in simultaneous conversion with DFSDM interface.

**25.3.33 Temperature sensor**

The temperature sensor can measure the ambient temperature ( $T_A$ ) of the device.

Main features

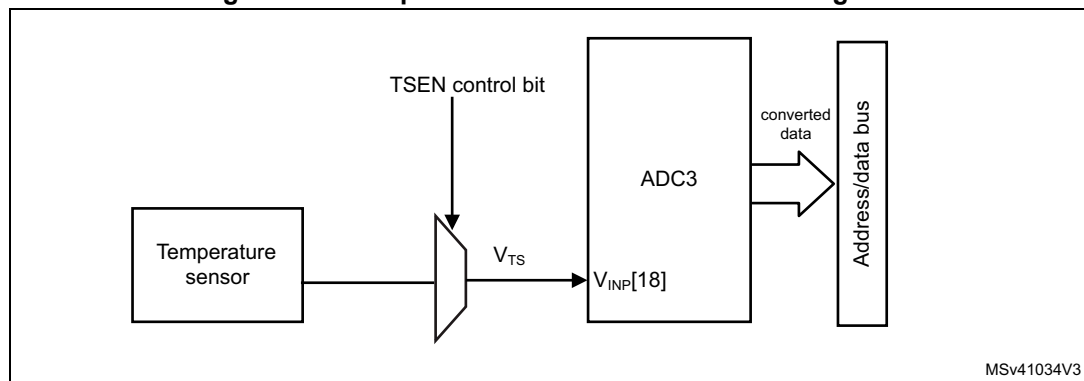

- Supported temperature range: -40 to 125 °C
- Precision: ±2 °C

The temperature sensor is internally connected to ADC3  $V_{INP}[18]$  input channel which is used to convert the sensor's output voltage to a digital value. The sampling time for the temperature sensor's analog pin must be greater than the stabilization time specified in the product datasheet.

When not in use, the sensor can be put in power-down mode.

Figure 191 shows the block diagram of the temperature sensor.

**Figure 191. Temperature sensor channel block diagram**

*Note:* The TSEN bit must be set to enable the conversion of internal channel ADC3  $V_{INP}[18]$  (temperature sensor,  $V_{TS}$ ).

### Reading the temperature

To use the sensor:

1. Select the ADC3  $V_{INP}[18]$  input channels (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the TSEN bit in the ADC3\_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting  $V_{TS}$  data in the ADC data register.
6. Calculate the actual temperature using the following formula:

$$\text{Temperature (in } ^\circ\text{C)} = \frac{110\text{ }^\circ\text{C} - 30\text{ }^\circ\text{C}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30\text{ }^\circ\text{C}$$

Where:

- TS\_CAL2 is the temperature sensor calibration value acquired at 110°C
  - TS\_CAL1 is the temperature sensor calibration value acquired at 30°C
  - TS\_DATA is the actual temperature sensor output value converted by ADC
- Refer to the device datasheet for more information about TS\_CAL1 and TS\_CAL2 calibration points.

*Note:* The sensor has a startup time after waking from power-down mode before it can output  $V_{TS}$  at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and TSEN bits should be set at the same time.

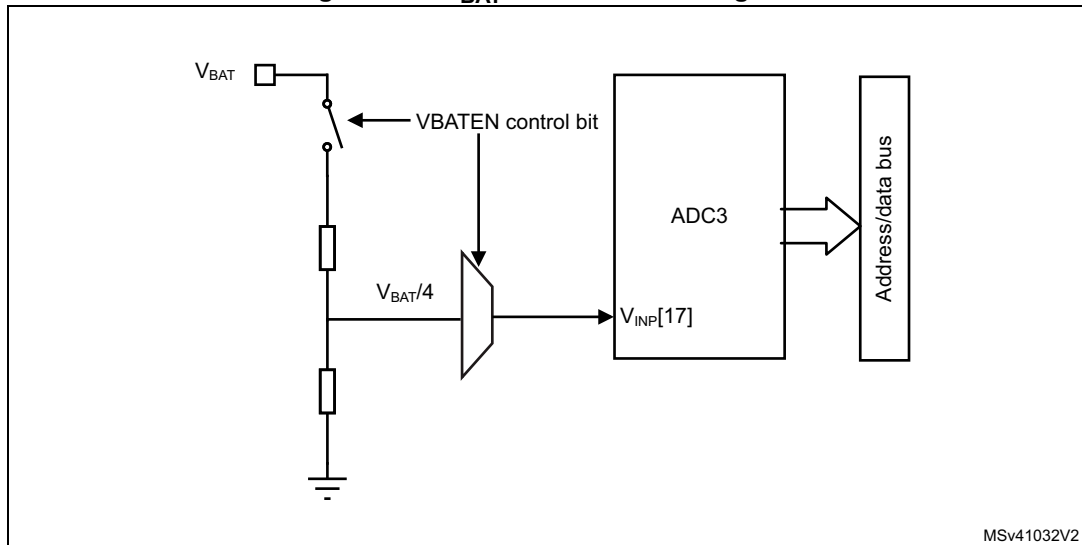

#### 25.3.34 $V_{BAT}$ supply monitoring

The VBATEN bit in the ADC3\_CCR register is used to switch to the battery voltage. As the  $V_{BAT}$  voltage could be higher than  $V_{DDA}$ , to ensure the correct operation of the ADC, the  $V_{BAT}$  pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect  $V_{BAT}/4$  to the ADC3  $V_{INP}[17]$  input channels. As a consequence, the converted digital value is one fourth of the  $V_{BAT}$  voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the  $V_{BAT}/4$  voltage.

*Figure 192* shows the block diagram of the  $V_{BAT}$  sensing feature.

Figure 192.  $V_{BAT}$  channel block diagram

Note: The  $VBATEN$  bit must be set to enable the conversion of internal channels ADC3  $V_{INP}[17]$  ( $V_{BAT}/4$ ).

### 25.3.35 Monitoring the internal voltage reference

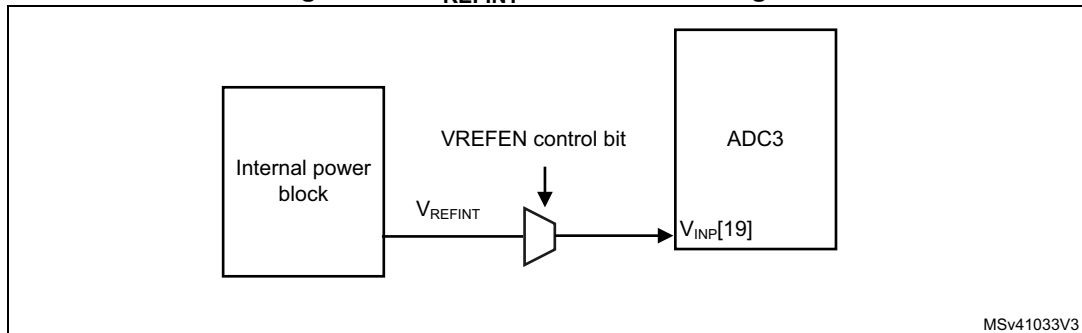

It is possible to monitor the internal voltage reference to have a reference point for evaluating the ADC  $V_{REF+}$  voltage level.

The internal voltage reference is internally connected to the input channel ADC3  $V_{INP}[19]$ .

The sampling time for this channel must be greater than the stabilization time specified in the product datasheet.

Figure 192 shows the block diagram of the  $V_{REFINT}$  sensing feature.

Figure 193.  $V_{REFINT}$  channel block diagram

Note: The  $VREFEN$  bit into  $ADCx\_CCR$  register must be set to enable the conversion of internal channels ADC3  $V_{INP}[19]$  ( $V_{REFINT}$ ).

### Calculating the actual $V_{DDA}$ voltage using the internal reference voltage

The  $V_{DDA}$  power supply voltage applied to the microcontroller may be subject to variation or not precisely known. The embedded internal voltage reference ( $V_{REFINT}$ ) and its calibration data acquired by the ADC during the manufacturing process at  $V_{DDA} = 3.3$  V can be used to evaluate the actual  $V_{DDA}$  voltage level.

The following formula gives the actual  $V_{DDA}$  voltage supplying the device:

$$V_{DDA} = 3.3 \text{ V} \times \text{VREFINT\_CAL} / \text{VREFINT\_DATA}$$

Where:

- VREFINT\_CAL is the VREFINT calibration value
- VREFINT\_DATA is the actual VREFINT output value converted by ADC

### Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the analog power supply and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent of  $V_{DDA}$ . For applications where  $V_{DDA}$  is known and ADC converted values are right-aligned you can use the following formula to get this absolute value:

$$V_{\text{CHANNEL}x} = \frac{V_{DDA}}{\text{FULL\_SCALE}} \times \text{ADCx\_DATA}$$

For applications where  $V_{DDA}$  value is not known, you must use the internal voltage reference and  $V_{DDA}$  can be replaced by the expression provided in [Section : Calculating the actual VDDA voltage using the internal reference voltage](#), resulting in the following formula:

$$V_{\text{CHANNEL}x} = \frac{3.3 \text{ V} \times \text{VREFINT\_CAL} \times \text{ADCx\_DATA}}{\text{VREFINT\_DATA} \times \text{FULL\_SCALE}}$$

Where:

- VREFINT\_CAL is the VREFINT calibration value
- ADCx\_DATA is the value measured by the ADC on channel x (right-aligned)
- VREFINT\_DATA is the actual VREFINT output value converted by the ADC
- FULL\_SCALE is the maximum digital value of the ADC output. For example with 16-bit resolution, it will be  $2^{16} - 1 = 65535$  or with 8-bit resolution,  $2^8 - 1 = 255$ .

*Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.*

## 25.4 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Table 202. ADC interrupts per each ADC

Interrupt event	Event flag	Enable control bit
ADC ready	ADRDY	ADRDYIE
End of conversion of a regular group	EOC	EOCIE
End of sequence of conversions of a regular group	EOS	EOSIE
End of conversion of a injected group	JEOC	JEOCIE
End of sequence of conversions of an injected group	JEOS	JEOSIE
Analog watchdog 1 status bit is set	AWD1	AWD1IE
Analog watchdog 2 status bit is set	AWD2	AWD2IE
Analog watchdog 3 status bit is set	AWD3	AWD3IE
End of sampling phase	EOSMP	EOSMPIE
Overrun	OVR	OVRIE
Injected context queue overflows	JQOVF	JQOVFIE

## 25.5 ADC registers (for each ADC)

Refer to [Section 1.1 on page 98](#) for a list of abbreviations used in register descriptions.

### 25.5.1 ADC interrupt and status register (ADCx\_ISR, x=1..3)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	JQOVF	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
					r_w1	r_w1	r_w1	r_w1	r_w1	r_w1	r_w1	r_w1	rc_w1	r_w1	r_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF**: Injected context queue overflow

This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to [Section 25.3.22: Queue of context for injected conversions](#) for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)

1: Injected context queue overflow has occurred

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADCx\_TR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADCx\_TR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADCx\_TR1 register. It is cleared by software writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS**: Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

**Bit 5 JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADCx\_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADCx\_JDRy register

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

**Bit 4 OVR:** ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

**Bit 3 EOS:** End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular Conversions sequence complete

**Bit 2 EOC:** End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADCx\_DR register. It is cleared by software writing 1 to it or by reading the ADCx\_DR register

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

**Bit 1 EOSMP:** End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

**Bit 0 ADRDY:** ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

### 25.5.2 ADC interrupt enable register (ADCx\_IER, x=1..3)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	JQOVF IE	AWD3 IE	AWD2 IE	AWD1 IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMP IE	ADRDY IE
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **JQOVFIE**: Injected context queue overflow interrupt enable

This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.

0: Injected Context Queue Overflow interrupt disabled

1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

*Note: Software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

*Note: Software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

**Bit 5 JEOCIE:** End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

*Note: Software is allowed to write this bit only when JADSTART=0 (which ensures that no regular conversion is ongoing).*

**Bit 4 OVRIE:** Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

**Bit 3 EOSIE:** End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

**Bit 2 EOCIE:** End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

**Bit 1 EOSMPIE:** End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

**Bit 0 ADRDYIE:** ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.3 ADC control register (ADCx\_CR, x=1..3)

Address offset: 0x08

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	ADCALDIF	DEEPPWD	ADVREGEN	LINCALRDYW6	LINCALRDYW5	LINCALRDYW4	LINCALRDYW3	LINCALRDYW2	LINCALRDYW1	Res.	Res.	Res.	Res.	Res.	ADCALIN
rs	rw	rw	rw	rw	rw	rw	rw	rw	rw						rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOST	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
							rw			rs	rs	rs	rs	rs	rs

**Bit 31 ADCAL:** ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.

It is cleared by hardware after calibration is complete.

0: Calibration complete

1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

*Note: Software is allowed to launch a calibration by setting ADCAL only when ADEN=0.*

*Note: Software is allowed to update the calibration factor by writing ADCx\_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)*

**Bit 30 ADCALDIF:** Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.

0: Writing ADCAL will launch a calibration in Single-ended inputs Mode.

1: Writing ADCAL will launch a calibration in Differential inputs Mode.

*Note: Software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

**Bit 29 DEEPPWD:** Deep-power-down enable

This bit is set and cleared by software to put the ADC in deep-power-down mode.

0: ADC not in deep-power down

1: ADC in deep-power-down (default reset state)

*Note: Software is allowed to write this bit only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

**Bit 28 ADVREGEN:** ADC voltage regulator enable

This bits is set by software to enable the ADC voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC Voltage regulator disabled

1: ADC Voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to [Section 25.3.6: ADC Deep-Power-Down Mode \(DEEPPWD\) & ADC Voltage Regulator \(ADVREGEN\)](#).

The software can program this bit field only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

**Bit 27 LINCALRDYW6:** Linearity calibration ready Word 6

This control / status bit allows to read/write the 6th linearity calibration factor.

When the linearity calibration is complete, this bit is set. A bit clear will launch the transfer of the linearity factor 6 into the LINCALFACT[29:0] of the ADC\_CALFACT2 register. The bit will be reset by hardware when the ADC\_CALFACT2 register can be read (software must poll the bit until it is cleared).

When the *LINCALRDYW6* bit is reset, a new linearity factor 6 value can be written into the LINCALFACT[29:0] of the ADC\_CALFACT2 register. A bit set will launch the linearity factor 6 update and the bit will be effectively set by hardware once the update will be done (software must poll the bit until it is set to indicate the write is effective).

*Note:* ADC\_CALFACT2[29:10] contains 0. ADC\_CALFACT2[9:0] corresponds linearity correction factor bits[159:150].

*Software is allowed to toggle this bit only if the LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged, see chapter 25.3.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADCx\_CALFACT) for details.*

*Software is allowed to update the linearity calibration factor by writing LINCALRDYWx only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)*

**Bit 26 LINCALRDYW5:** Linearity calibration ready Word 5

Refer to LINCALRDYW6 description.

*Note:* ADC\_CALFACT2[29:0] corresponds linearity correction factor bits[149:120].

*Software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.*

**Bit 25 LINCALRDYW4:** Linearity calibration ready Word 4

Refer to LINCALRDYW6 description.

*Note:* ADC\_CALFACT2[29:0] correspond linearity correction factor bits[119:90].

*Software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.*

**Bit 24 LINCALRDYW3:** Linearity calibration ready Word 3

Refer to LINCALRDYW6 description.

*Note:* ADC\_CALFACT2[29:0] corresponds linearity correction factor bits[89:60].

*Software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.*

**Bit 23 LINCALRDYW2:** Linearity calibration ready Word 2

Refer to LINCALRDYW6 description.

*Note:* ADC\_CALFACT2[29:0] corresponds linearity correction factor bits[59:30].

*Software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW1 bits are left unchanged.*

**Bit 22 LINCALRDYW1:** Linearity calibration ready Word 1

Refer to LINCALRDYW6 description.

*Note:* ADC\_CALFACT2[29:0] corresponds linearity correction factor bits[29:0].

*Software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW2 bits are left unchanged.*

Bits 21:17 Reserved, must be kept at reset value.

**Bit 16 ADCALLIN:** Linearity calibration

This bit is set and cleared by software to enable the Linearity calibration.

0: Writing ADCAL will launch a calibration without the Linearity calibration.

1: Writing ADCAL will launch a calibration with the Linearity calibration.

*Note: Software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 15:9 Reserved, must be kept at reset value.

**Bit 8 BOOST:** Boost mode control

This bit is set and cleared by software to enable/disable the Boost mode.

0: Boost mode off. Used when ADC clock < 20 MHz to save power at lower clock frequency.

1: Boost mode on. Must be used when ADC clock > 20 MHz.

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

*When dual mode is enabled (bits DAMDF of ADCx\_CCR register are not equal to zero), the bit BOOST of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.*

Bits 7:6 Reserved, must be kept at reset value.

**Bit 5 JADSTP:** ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note: Software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).*

*In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)*

**Bit 4 ADSTP:** ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note: Software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).*

*In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).*

*In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.*

**Bit 3 JADSTART:** ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion will start immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

*Note: Software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).*

*In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)*

**Bit 2 ADSTART:** ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion will start immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode (CONT=0, DISCEN=0) when software trigger is selected (EXTEN=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN=1), when the software trigger is selected (EXTEN=0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note: Software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)*

*In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)*

**Bit 1 ADDIS:** ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note: Software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

**Bit 0 ADEN:** ADC enable control

This bit is set by software to enable the ADC. The ADC will be effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

*Note: Software is allowed to set ADEN only when all bits of ADCx\_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)*

**25.5.4 ADC configuration register (ADCx\_CFGR, x=1..3)**

Address offset: 0x0C

Bit 31 **JQDIS**: Injected Queue disable

These bits are set and cleared by software to disable the Injected Queue mechanism :

- 0: Injected Queue enabled
- 1: Injected Queue disabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).*

*A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.*

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

- 00000: ADC analog input channel-0 monitored by AWD1
- 00001: ADC analog input channel-1 monitored by AWD1
- .....
- 10010: ADC analog input channel-19 monitored by AWD1
- others: reserved, must not be used

*Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.*

*Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 25 **JAUTO**: Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

- 0: Automatic injected group conversion disabled
- 1: Automatic injected group conversion enabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).*

*When dual mode is enabled (DAMDF bits in ADCx\_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.*

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

- 0: Analog watchdog 1 disabled on injected channels
- 1: Analog watchdog 1 enabled on injected channels

*Note: Software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

- Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels  
 This bit is set and cleared by software  
 0: Analog watchdog 1 disabled on regular channels  
 1: Analog watchdog 1 enabled on regular channels  
*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*
- Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels  
 This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels  
 0: Analog watchdog 1 enabled on all channels  
 1: Analog watchdog 1 enabled on a single channel  
*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
- Bit 21 **JQM**: JSQR queue mode  
 This bit is set and cleared by software.  
 It defines how an empty Queue is managed.  
 0: JSQR Mode 0: The Queue is never empty and maintains the last written configuration into JSQR.  
 1: JSQR Mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.  
 Refer to [Section 25.3.22: Queue of context for injected conversions](#) for more information.  
*Note: Software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*  
 When dual mode is enabled (DAMDF bits in ADCx\_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.
- Bit 20 **JDISCEN**: Discontinuous mode on injected channels  
 This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.  
 0: Discontinuous mode on injected channels disabled  
 1: Discontinuous mode on injected channels enabled  
*Note: Software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*  
 It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.  
 When dual mode is enabled (bits DAMDF of ADCx\_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.
- Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count  
 These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.  
 000: 1 channel  
 001: 2 channels  
 ...  
 111: 8 channels  
*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*  
 When dual mode is enabled (DAMDF bits in ADCx\_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

*Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.*

*It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.*

*Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

*When dual mode is enabled (DAMDF bits in ADCx\_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.*

## Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off

1: Auto-delayed conversion mode on

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

*When dual mode is enabled (DAMDF bits in ADCx\_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.*

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

*Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.*

*Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

*When dual mode is enabled (DAMDF bits in ADCx\_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.*

Bit 12 **OVRMOD**: Overrun Mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADCx\_DR register is preserved with the old data when an overrun is detected.

1: ADCx\_DR register is overwritten with the last conversion result when an overrun is detected.

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: Event 0  
00001: Event 1  
00010: Event 2  
00011: Event 3  
00100: Event 4  
00101: Event 5  
00110: Event 6  
00111: Event 7  
...  
11111: Event 31

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 4:2 **RES[2:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

000: 16-bit  
001: 14-bit  
010: 12-bit  
011: 10-bit  
100: 8-bit  
All other codes reserved

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 1:0 **DMNGT[1:0]**: Data Management configuration

This bit is set and cleared by software to select how ADC interface output data are managed.

00: Regular conversion data stored in DR only  
01: DMA One Shot Mode selected  
10: DFSDM mode selected  
11: DMA Circular Mode selected

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

*In dual-ADC modes, this bit is not relevant and replaced by control bit DAMDF of the ADC<sub>x</sub>\_CCR register.*

### 25.5.5 ADC configuration register 2 (ADCx\_CFGR2, x=1..3)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

- 0000: No left shift
- 0001: Shift left 1-bit
- 0010: Shift left 2-bits
- 0011: Shift left 3-bits
- 0100: Shift left 4-bits
- 0101: Shift left 5-bits
- 0110: Shift left 6-bits
- 0111: Shift left 7-bits
- 1000: Shift left 8-bits
- 1001: Shift left 9-bits
- 1010: Shift left 10-bits
- 1011: Shift left 11-bits
- 1100: Shift left 12-bits
- 1101: Shift left 13-bits
- 1101: Shift left 14-bits
- 1111: Shift left 15-bits

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

- 0: 1x (no oversampling)
- 1: 2x
- 2: 3x
- ...
- 1023: 1024x

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RSHIFT4**: Right-shift data after Offset 4 correction

Refer to RSHIFT1 description.

Bit 13 **RSHIFT3**: Right-shift data after Offset 3 correction  
Refer to RSHIFT1 description

Bit 12 **RSHIFT2**: Right-shift data after Offset 2 correction  
Refer to RSHIFT1 description

Bit 11 **RSHIFT1**: Right-shift data after Offset 1 correction

This bitfield is set and cleared by software to right-shift 1-bit data after offset1 correction. This bit can only be used for 8-bit and 16-bit data format (see [Section : Data register, data alignment and offset \(ADCx\\_DR, ADCx\\_JDRy, OFFSETy, OFFSETy\\_CH, OVSS, LSHIFT, RSHIFT, SSATE\)](#) for details).

0: Right-shifting disabled

1: Data is right-shifted 1-bit.

Bit 10 **ROVSM**: Regular Oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bit 9 **TROVS**: Triggered Regular Oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

*Note: Software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bits 8:5 **OVSS[3:0]**: Oversampling right shift

This bit field is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No right shift

0001: Shift right 1-bit

0010: Shift right 2-bits

0011: Shift right 3-bits

0100: Shift right 4-bits

0101: Shift right 5-bits

0110: Shift right 6-bits

0111: Shift right 7-bits

1000: Shift right 8-bits

1001: Shift right 9-bits

1010: Shift right 10-bits

1011: Shift right 11-bits

Other codes reserved

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **JOVSE**: Injected Oversampling Enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected Oversampling disabled

1: Injected Oversampling enabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

Bit 0 **ROVSE**: Regular Oversampling Enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular Oversampling disabled

1: Regular Oversampling enabled

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

### 25.5.6 ADC sample time register 1 (ADCx\_SMPR1, x=1..3)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 1.5 ADC clock cycles

001: 2.5 ADC clock cycles

010: 8.5 ADC clock cycles

011: 16.5 ADC clock cycles

100: 32.5 ADC clock cycles

101: 64.5 ADC clock cycles

110: 387.5 ADC clock cycles

111: 810.5 ADC clock cycles

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.7 ADC sample time register 2 (ADCx\_SMPR2, x=1..3)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP19[2:0]			SMP18[2:0]			SMP17[2:0]			SMP16[2:0]			SMP15[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP15[0]	SMP14[2:0]			SMP13[2:0]			SMP12[2:0]			SMP11[2:0]			SMP10[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

- 000: 1.5 ADC clock cycles
- 001: 2.5 ADC clock cycles
- 010: 8.5 ADC clock cycles
- 011: 16.5 ADC clock cycles
- 100: 32.5 ADC clock cycles
- 101: 64.5 ADC clock cycles
- 110: 387.5 ADC clock cycles
- 111: 810.5 ADC clock cycles

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.8 ADC pre channel selection register (ADCx\_PCSEL, x=1..3)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCSEL19	PCSEL18	PCSEL17	PCSEL16
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCSEL15	PCSEL14	PCSEL13	PCSEL12	PCSEL11	PCSEL10	PCSEL9	PCSEL8	PCSEL7	PCSEL6	PCSEL5	PCSEL4	PCSEL3	PCSEL2	PCSEL1	PCSEL0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 PCSELx: Channel x ( $V_{INP[i]}$ ) pre selection

These bits are written by software to pre select the input channel at IO instance to be converted.

0: Input Channel x ( $V_{inp x}$ ) is not pre selected for conversion, the ADC conversion result with this channel shows wrong result.

1: Input Channel x ( $V_{inp x}$ ) is pre selected for conversion

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.9 ADC watchdog threshold register 1 (ADCx\_LTR1, x=1..3)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	LTR1[25:16]

LTR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 LTR1[25:0]: Analog watchdog 1 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 1.

Refer to [Section 25.3.30: Analog window watchdog \(AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\\_HTRy, AWD\\_LTRy, AWDy\)](#)

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

**25.5.10 ADC watchdog threshold register 1 (ADCx\_LHTR1, x=1..3)**

Address offset: 0x24

Reset value: 0x03FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	HTR1[25:16]									
						r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HTR1[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **HTR1[25:0]**: Analog watchdog 1 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 1.

Refer to [Section 25.3.30: Analog window watchdog \(AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\\_HTRy, AWD\\_LTRy, AWDy\)](#)

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.11 ADC regular sequence register 1 (ADCx\_SQR1, x=1..3)

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ4[4:0]					Res.	SQ3[4:0]					Res.	SQ2[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ2[3:0]			Res.	SQ1[4:0]					Res.	Res.	L[3:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]**: 4th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the regular conversion sequence.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]**: 3rd conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]**: 2nd conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]**: 1st conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]**: Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

### 25.5.12 ADC regular sequence register 2 (ADCx\_SQR2, x=1..3)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ9[4:0]					Res.	SQ8[4:0]					Res.	SQ7[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ7[3:0]			Res.	SQ6[4:0]					Res.	SQ5[4:0]					
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]**: 9th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 9th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]**: 8th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 8th in the regular conversion sequence

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]**: 7th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 7th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]**: 6th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 6th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]**: 5th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 5th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

### 25.5.13 ADC regular sequence register 3 (ADCx\_SQR3, x=1..3)

Address offset: 0x38

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SQ12[3:0]			Res.	SQ11[4:0]					Res.	SQ10[4:0]					
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]**: 14th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 14th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]**: 13th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 13th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]**: 12th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 12th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]**: 11th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 11th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]**: 10th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 10th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

**25.5.14 ADC regular sequence register 4 (ADCx\_SQR4, x=1..3)**

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SQ16[4:0]					Res.	SQ15[4:0]				
					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]**: 16th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 16th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]**: 15th conversion in regular sequence

These bits are written by software with the channel number (0..19) assigned as the 15th in the regular conversion sequence.

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

### 25.5.15 ADC regular Data Register (ADCx\_DR, x=1..3)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular Data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in [Section 25.3.27: Data management](#).

**25.5.16 ADC injected sequence register (ADCx\_JSQR, x=1..3)**

Address offset: 0x4C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]				
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JL[1:0]		
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:27 **JSQ4[4:0]**: 4th conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 4th in the injected conversion sequence.

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]**: 3rd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 3rd in the injected conversion sequence.

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]**: 2nd conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 2nd in the injected conversion sequence.

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]**: 1st conversion in the injected sequence

These bits are written by software with the channel number (0..19) assigned as the 1st in the injected conversion sequence.

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

Bits 8:7 **JEXTEN[1:0]**: External Trigger Enable and Polarity Selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled

00: If JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

*If JQM=1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to [Section 25.3.22: Queue of context for injected conversions](#))*

Bits 6:2 **JEXTSEL[4:0]**: External Trigger Selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: Event 0

00001: Event 1

00010: Event 2

00011: Event 3

00100: Event 4

00101: Event 5

00110: Event 6

00111: Event 7

...

11111: Event 31:

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

Bits 1:0 **JL[1:0]**: Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

*Note: Software is allowed to write these bits at any time, once the ADC is enabled (ADEN=1).*

### 25.5.17 ADC offset register (ADCx\_OFRy, x=1..3) (y=1..4)

Address offset: 0x60, 0x64, 0x68, 0x6C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SSATE	OFFSETy_CH[4:0]					OFFSETy[25:16]									
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSETy[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bit 31 **SSATE**: Signed saturation Enable

This bit is written by software to enable or disable the Signed saturation feature.

This bit can be enabled only for 8-bit and 16-bit data format (see [Section : Data register, data alignment and offset \(ADCx\\_DR, ADCx\\_JDRy, OFFSETy, OFFSETy\\_CH, OVSS, LSHIFT, RSHIFT, SSATE\)](#) for details).

0: Offset is subtracted maintaining data integrity and extending result size (9-bit and 17-bit signed format).

1: Offset is subtracted and result is saturated to maintain result size.

*Note: Software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 30:26 **OFFSETy\_CH[4:0]**: Channel selection for the Data offset y

These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[25:0] will apply.

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 25:0 **OFFSETy[25:0]**: Data offset y for the channel programmed into bits OFFSETy\_CH[4:0]

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy\_CH[4:0]. The conversion result can be read from in the ADCx\_DR (regular conversion) or from in the ADCx\_JDRyi registers (injected conversion).

When OFFSETy[25:0] bitfield is reset, the offset compensation is disabled.

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

*If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.*

*Ex: if OFFSET1\_CH[4:0]=4 and OFFSET2\_CH[4:0]=4, this is OFFSET1[25:0] which is subtracted when converting channel 4.*

### 25.5.18 ADC injected data register (ADCx\_JDRy, x=1..3, y= 1..4)

Address offset: 0x80 - 0x8C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **JDATA[31:0]**: Injected data

These bits are read-only. They contain the conversion result from injected channel y. The data are left -or right-aligned as described in [Section 25.3.27: Data management](#).

### 25.5.19 ADC Analog Watchdog 2 Configuration Register (ADCx\_AWD2CR, x=1..3)

Address offset: 0xA0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWD2CH[19:16]			
												r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AWD2CH[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2

AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2

When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

*Note: The channels selected by AWD2CH must be also selected into the SQRi or JSQRi registers.*

*Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.20 ADC Analog Watchdog 3 Configuration Register (ADCx\_AWD3CR, x=1..3)

Address offset: 0xA4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWD3CH[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AWD3CH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWD2CH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2

AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2

When AWD2CH[19:0] = 000..0, the analog Watchdog 2 is disabled

*Note: The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers.*

*Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.21 ADC watchdog lower threshold register 2 (ADCx\_LTR2, x=1..3)

Address offset: 0xB0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	LTR2[25:16]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LTR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **LTR2[25:0]**: Analog watchdog 2 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 2.

Refer to [Section 25.3.30: Analog window watchdog \(AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\\_HTRy, AWD\\_LTRy, AWDy\)](#).

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.22 ADC watchdog higher threshold register 2 (ADCx\_HTR2, x=1..3)

Address offset: 0xB4

Reset value: 0x03FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	HTR2[25:16]

HTR2[15:0]															
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **HTR2[25:0]**: Analog watchdog 2 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 2.

Refer to [Section 25.3.30: Analog window watchdog \(AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\\_HTRy, AWD\\_LTRy, AWDy\)](#).

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.23 ADC watchdog lower threshold register 3 (ADCx\_LTR3, x=1..3)

Address offset: 0xB8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LTR3[15:0]															
rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW	rW

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **LTR3[25:0]**: Analog watchdog 3 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 3.

Refer to [Section 25.3.30: Analog window watchdog \(AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\\_HTRy, AWD\\_LTRy, AWDy\)](#).

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.24 ADC watchdog higher threshold register 3 (ADCx\_HTR3, x=1..3)

Address offset: 0xBC

Reset value: 0x03FF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	HTR3[25:16]									
						r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HTR3[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 **HTR3[25:0]**: Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3.

Refer to [Section 25.3.30: Analog window watchdog \(AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD\\_HTRy, AWD\\_LTRy, AWDy\)](#)

*Note: Software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

### 25.5.25 ADC Differential Mode Selection register (ADCx\_DIFSEL, x=1..3)

Address offset: 0xC0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIFSEL[19:16]			
												r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIFSEL[15:0]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]**: Differential mode for channels 19 to 0

These bits are set and cleared by software. They allow to select if a channel is configured as single ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel-i is configured in single ended mode

DIFSEL[i] = 1: ADC analog input channel-i is configured in differential mode

*Note: Software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

### 25.5.26 ADC Calibration Factors register (ADCx\_CALFACT, x=1..3)

Address offset: 0xC4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	CALFACT_D[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CALFACT_S[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 **CALFACT\_D[10:0]**: Calibration Factors in differential mode

These bits are written by hardware or by software.

Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new differential calibration is launched.

*Note: Software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).*

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **CALFACT\_S[10:0]**: Calibration Factors In Single-Ended mode

These bits are written by hardware or by software.

Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended calibration is launched.

*Note: Software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).*

### 25.5.27 ADC Calibration Factor register 2 (ADCx\_CALFACT2, x=1..3)

Address offset: 0xC8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LINCALFACT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **LINCALFACT[29:0]**: Linearity Calibration Factor

These bits are written by hardware or by software.

They hold 30-bit out of the 160-bit linearity calibration factor.

Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.

Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended calibration is launched.

*Note: Software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).*

### 25.5.28 ADC Option register (ADCx\_OR, x=1..3)

Address offset: 0xD0

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:0 Reserved, must be kept at reset value.

## 25.6 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

### 25.6.1 ADC Common status register (ADCx\_CSR, x=12 or 3)

Address offset: 0x00 (this offset address is relative to the master ADC base address + 0x300)

Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADCx\_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					r	r	r	r	r	r	r	r	r	r	r

Bits 31:27 Reserved, must be kept at reset value.

- Bit 26 **JQOVF\_SLV**: Injected Context Queue Overflow flag of the slave ADC  
This bit is a copy of the JQOVF bit in the corresponding ADCx+1\_ISR register.
- Bit 25 **AWD3\_SLV**: Analog watchdog 3 flag of the slave ADC  
This bit is a copy of the AWD3 bit in the corresponding ADCx+1\_ISR register.
- Bit 24 **AWD2\_SLV**: Analog watchdog 2 flag of the slave ADC  
This bit is a copy of the AWD2 bit in the corresponding ADCx+1\_ISR register.
- Bit 23 **AWD1\_SLV**: Analog watchdog 1 flag of the slave ADC  
This bit is a copy of the AWD1 bit in the corresponding ADCx+1\_ISR register.
- Bit 22 **JEOS\_SLV**: End of injected sequence flag of the slave ADC  
This bit is a copy of the JEOS bit in the corresponding ADCx+1\_ISR register.
- Bit 21 **JEOC\_SLV**: End of injected conversion flag of the slave ADC  
This bit is a copy of the JEOC bit in the corresponding ADCx+1\_ISR register.
- Bit 20 **OVR\_SLV**: Overrun flag of the slave ADC  
This bit is a copy of the OVR bit in the corresponding ADCx+1\_ISR register.
- Bit 19 **EOS\_SLV**: End of regular sequence flag of the slave ADC  
This bit is a copy of the EOS bit in the corresponding ADCx+1\_ISR register.
- Bit 18 **EOC\_SLV**: End of regular conversion of the slave ADC  
This bit is a copy of the EOC bit in the corresponding ADCx+1\_ISR register.
- Bit 17 **EOSMP\_SLV**: End of Sampling phase flag of the slave ADC  
This bit is a copy of the EOSMP2 bit in the corresponding ADCx+1\_ISR register.
- Bit 16 **ADRDY\_SLV**: Slave ADC ready  
This bit is a copy of the ADRDY bit in the corresponding ADCx+1\_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

- Bit 10 **JQOVF\_MST**: Injected Context Queue Overflow flag of the master ADC  
This bit is a copy of the JQOVF bit in the corresponding ADCx\_ISR register.
- Bit 9 **AWD3\_MST**: Analog watchdog 3 flag of the master ADC  
This bit is a copy of the AWD3 bit in the corresponding ADCx\_ISR register.
- Bit 8 **AWD2\_MST**: Analog watchdog 2 flag of the master ADC  
This bit is a copy of the AWD2 bit in the corresponding ADCx\_ISR register.
- Bit 7 **AWD1\_MST**: Analog watchdog 1 flag of the master ADC  
This bit is a copy of the AWD1 bit in the corresponding ADCx\_ISR register.
- Bit 6 **JEOS\_MST**: End of injected sequence flag of the master ADC  
This bit is a copy of the JEOS bit in the corresponding ADCx\_ISR register.
- Bit 5 **JEOC\_MST**: End of injected conversion flag of the master ADC  
This bit is a copy of the JEOC bit in the corresponding ADCx\_ISR register.
- Bit 4 **OVR\_MST**: Overrun flag of the master ADC  
This bit is a copy of the OVR bit in the corresponding ADCx\_ISR register.
- Bit 3 **EOS\_MST**: End of regular sequence flag of the master ADC  
This bit is a copy of the EOS bit in the corresponding ADCx\_ISR register.
- Bit 2 **EOC\_MST**: End of regular conversion of the master ADC  
This bit is a copy of the EOC bit in the corresponding ADCx\_ISR register.
- Bit 1 **EOSMP\_MST**: End of Sampling phase flag of the master ADC  
This bit is a copy of the EOSMP bit in the corresponding ADCx\_ISR register.
- Bit 0 **ARDY\_MST**: Master ADC ready  
This bit is a copy of the ARDY bit in the corresponding ADCx\_ISR register.

### 25.6.2 ADC common control register (ADCx\_CCR, x=12 or 3)

Address offset: 0x08 (this offset address is relative to the master ADC base address + 0x300)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	VBATEN	TSEN	VREFEN	PRESC[3:0]				CKMODE[1:0]	
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAMDF[1:0]		Res.	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **VBATEN**: VBAT enable

This bit is set and cleared by software to control the channel 17 of ADC3

0: V<sub>BAT</sub> channel disabled

1: V<sub>BAT</sub> channel enabled

*Note: Software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bit 23 **TSEN**: Temperature sensor enable

This bit is set and cleared by software to control the channel 18 of ADC3

0: Temperature sensor channel disabled

1: Temperature sensor channel enabled

*Note: Software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bit 22 **VREFEN**: V<sub>REFINT</sub> enable

This bit is set and cleared by software to enable/disable the V<sub>REFINT</sub> channel.

0: V<sub>REFINT</sub> channel disabled

1: V<sub>REFINT</sub> channel enabled

*Note: Software is allowed to write this bit only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 21:18 **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC.

The clock is common for all the ADCs.

0000: input ADC clock not divided

0001: input ADC clock divided by 2

0010: input ADC clock divided by 4

0011: input ADC clock divided by 6

0100: input ADC clock divided by 8

0101: input ADC clock divided by 10

0110: input ADC clock divided by 12

0111: input ADC clock divided by 16

1000: input ADC clock divided by 32

1001: input ADC clock divided by 64

1010: input ADC clock divided by 128

1011: input ADC clock divided by 256

other: reserved

*Note: Software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.*

Bits 17:16 **CKMODE[1:0]**: ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

00: CK\_ADCx (x=123) (Asynchronous clock mode), generated at product level (refer to [Section 8: Reset and Clock Control \(RCC\)](#))

01: adc\_hclk/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC\_CFGR register) and if the system clock has a 50% duty cycle.

10: adc\_hclk/2 (Synchronous clock mode)

11: adc\_hclk/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note: Software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 15:14 **DAMDF[1:0]**: Dual ADC Mode Data Format

This bit-field is set and cleared by software. It specifies the data format in the common data register ADCx\_CDR.

00: Dual ADC mode without data packing (ADCx\_CDR and ADCx\_CDR2 registers not used).

01: Reserved

10: Data formatting mode for 32 down to 10-bit resolution

11: Data formatting mode for 8-bit resolution

*Note: Software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

## Bits 13:12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY**: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to [Table 203](#) for the value of ADC resolution versus DELAY bits values.

*Note: Software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode.

All the ADCs independent:

00000: Independent mode

00001 to 01001: Dual mode, master and slave ADCs working together

00001: Combined regular simultaneous + injected simultaneous mode

00010: Combined regular simultaneous + alternate trigger mode

00011: Combined Interleaved mode + injected simultaneous mode

00100: Reserved

00101: Injected simultaneous mode only

00110: Regular simultaneous mode only

00111: Interleaved mode only

01001: Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note: Software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

**Table 203. DELAY bits versus ADC resolution**

DELAY bits	16-bit resolution	14-bit resolution	12-bit resolution	10-bit resolution	8-bit resolution

### 25.6.3 ADC common regular data register for dual mode (ADCx\_CDR, x=12 or 3)

Address offset: 0x0C (this offset address is relative to the master ADC base address + 0x300)

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]																
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA_MST[15:0]																
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA\_SLV[15:0]**: Regular data of the slave ADC  
 In dual mode, these bits contain the regular data of the slave ADC. Refer to [Section 25.3.32: Dual ADC modes](#).  
 The data alignment is applied as described in [Section : Data register, data alignment and offset \(ADCx\\_DR, ADCx\\_JDRy, OFFSETy, OFFSETy\\_CH, OVSS, LSHIFT, RSHIFT, SSATE\)](#)

Bits 15:0 **RDATA\_MST[15:0]**: Regular data of the master ADC.  
 In dual mode, these bits contain the regular data of the master ADC. Refer to [Section 25.3.32: Dual ADC modes](#).  
 The data alignment is applied as described in [Section : Data register, data alignment and offset \(ADCx\\_DR, ADCx\\_JDRy, OFFSETy, OFFSETy\\_CH, OVSS, LSHIFT, RSHIFT, SSATE\)](#)  
 In MDMA=0b11 mode, bits 15:8 contains SLV\_ADC\_DR[7:0], bits 7:0 contains MST\_ADC\_DR[7:0].

### 25.6.4 ADC common regular data register for 32-bit dual mode (ADCx\_CDR2, x=12 or 3)

Address offset: 0x10 (this offset address is relative to the master ADC base address + 0x300)

Reset value: 0x0000 0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDATA_ALT[15:0]																
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA\_ALT[31:0]**: Regular data of the master/slave alternated ADCs  
 In dual mode, these bits alternatively contains the regular 32-bit data of the master and the slave ADC. Refer to [Section 25.3.32: Dual ADC modes](#).  
 The data alignment is applied as described in [Section : Data register, data alignment and offset \(ADCx\\_DR, ADCx\\_JDRy, OFFSETy, OFFSETy\\_CH, OVSS, LSHIFT, RSHIFT, SSATE\)](#).

### 25.6.5 ADC register map

The following table summarizes the ADC registers.

**Table 204. ADC global register map**

Offset	Register
0x000 - 0x0D0	Master ADC1 or Master ADC3
0x0D4 - 0x0FC	Reserved
0x100 - 0x1D0	Slave ADC2
0x1D4 - 0x2FC	Reserved
0x300 - 0x310	Master and slave ADCs common registers (ADC12 or ADC3)

**Table 205. ADC register map and reset values for each ADC (offset=0x000 for master ADC, 0x100 for slave ADC)**

## 26 Digital-to-analog converter (DAC)

### 26.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC has two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin,  $V_{REF+}$  (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to *voltage reference buffer (VREFBUF)* section.

The DAC\_OUTx pin can be used as general purpose Input/Output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to allow a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode; the sample and hold mode.

### 26.2 DAC main features

The DAC main features are the following (see [Figure 194: DAC channel block diagram](#))

- Two DAC converters: one output channel each
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- buffer offset calibration
- Each DAC output can be disconnected from the DAC\_OUTx output pin
- DAC output connection to on chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from  $V_{REF+}$  pin or internal VREFBUF reference

[Figure 194](#) shows the block diagram of a DAC channel and [Table 207](#) gives the pin description.

## 26.3 DAC functional description

### 26.3.1 DAC block diagram

Figure 194. DAC channel block diagram

1. The output mode controller switches between the normal mode in buffer/unbuffered configuration and the Sample and Hold mode.

### 26.3.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DAC\_OUTx can be disconnected from output pin and used as ordinary GPIO
- The DAC\_OUTx can used internal pin connection to on-chip peripherals such as comparators and OPAMPs.
- DAC output channel buffered or non buffered
- Sample and hold block and registers using LSI clock source (lsi\_ck) and operational in Stop mode for static conversion

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as COMP, OPAMP and ADC. In this case, the DAC output channel can be disconnected from the DAC\_OUTx output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The sample and hold block and its associated registers can run in Stop mode using the LSI clock source (lsi\_ck).

**Table 207. DAC pins**

Name	Signal type	Remarks
V <sub>REF+</sub>	Input, analog reference positive	The higher/positive reference voltage for the DAC, $V_{DDAmin} \leq V_{REF+} \leq V_{DDA}$ (refer to datasheet)
V <sub>DDA</sub>	Input, analog supply	Analog power supply
V <sub>SSA</sub>	Input, analog supply ground	Ground for analog power supply
DAC_OUTx	Analog output signal	DAC channelx analog output

**Table 208. DAC internal signals**

Internal signal name	Signal type	Description
dac_ch1_dma	Digital input/output	DAC channel 1 DMA request
dac_ch2_dma	Digital input/output	DAC channel 2 DMA request
dac_ch1_trg[0:15]	Digital inputs	DAC channel 1
dac_ch2_trg[0:15]	Digital inputs	DAC channel 2
dac_unr_it	Digital output	DAC underrun interrupt
dac_pclk	Digital input	DAC peripheral clock
dac_out1	Analog output	DAC channel 1 output for on-chip peripherals
dac_out2	Analog output	DAC channel 2 output for on-chip peripherals

### 26.3.3 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC\_CR register. The DAC channel is then enabled after a startup time  $t_{WAKEUP}$ .

*Note:* The ENx bit enables the analog DAC Channelx only. The DAC Channelx digital interface is enabled even if the ENx bit is reset.

### 26.3.4 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channelx, there are three possibilities:
  - 8-bit right alignment: the software has to load data into the DAC\_DHR8Rx [7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC\_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC\_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC\_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

**Figure 195. Data registers in single DAC channel mode**

- Dual DAC channels (when available), there are three possibilities:
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC\_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC\_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC\_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 196. Data registers in dual DAC channel mode

### 26.3.5 DAC conversion

The DAC\_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC\_DHRx register (write to DAC\_DHR8Rx, DAC\_DHR12Lx, DAC\_DHR12Rx, DAC\_DHR8RD, DAC\_DHR12RD or DAC\_DHR12LD).

Data stored in the DAC\_DHRx register are automatically transferred to the DAC\_DORx register after one dac\_pclk clock cycle, if no hardware trigger is selected (TENx bit in DAC\_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC\_CR register is set) and a trigger occurs, the transfer is performed three dac\_pclk clock cycles later.

When DAC\_DORx is loaded with the DAC\_DHRx contents, the analog output voltage becomes available after a time  $t_{SETTLING}$  that depends on the power supply voltage and the analog output load.

Figure 197. Timing diagram for conversion with trigger disabled TEN = 0

### 26.3.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and  $V_{REF+}$ .

The analog output voltages on each DAC channel pin are determined by the following equation:

$$DAC_{output} = V_{REF} \times \frac{DOR}{4096}$$

### 26.3.7 DAC trigger selection

If the TENx control bit is set, conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events will trigger conversion as shown in bits TSEL1[3:0] and TSEL2[3:0] in [Section 26.5.1: DAC control register \(DAC\\_CR\)](#).

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC\_DHRx register are transferred into the DAC\_DORx register. The DAC\_DORx register is updated three dac\_pclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC\_DORx register has been loaded with the DAC\_DHRx register contents.

*Note:* TSELx[3:0] bit cannot be changed when the ENx bit is set.

*When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DORx register takes only one APB clock cycle.*

**Table 209. DAC trigger selection**

Source	Type	TSELx[3:0]
SWTRIG	Software control bit	0000
TIM1_TRGO	Internal signal from on-chip timers	0001
TIM2_TRGO	Internal signal from on-chip timers	0010

LPTIM2_OUT	Internal signal from on-chip timers	1100
EXTI9	External pin	1101
Reserved	-	1110
Reserved	-	1111

### 26.3.8 DMA request

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

A DAC DMA request is generated when an external trigger (but not a software trigger) occurs while the DMAENx bit is set. The value of the DAC\_DHRx register is then transferred into the DAC\_DORx register.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, you should set only the corresponding DMAENx bit. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

#### DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC\_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

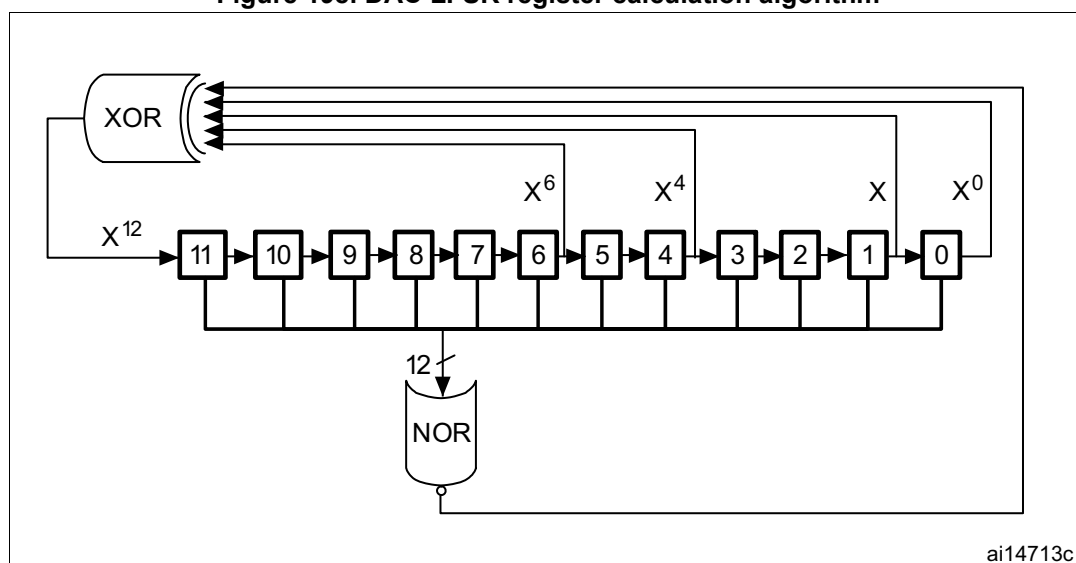

The software should clear the DMAUDRx flag by writing “1”, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software should modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC\_CR register is enabled.

### 26.3.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to “01”. The preloaded value in LFSR is 0xAAA. This register is updated three dac\_pclk clock cycles after each trigger event, following a specific calculation algorithm.

Figure 198. DAC LFSR register calculation algorithm

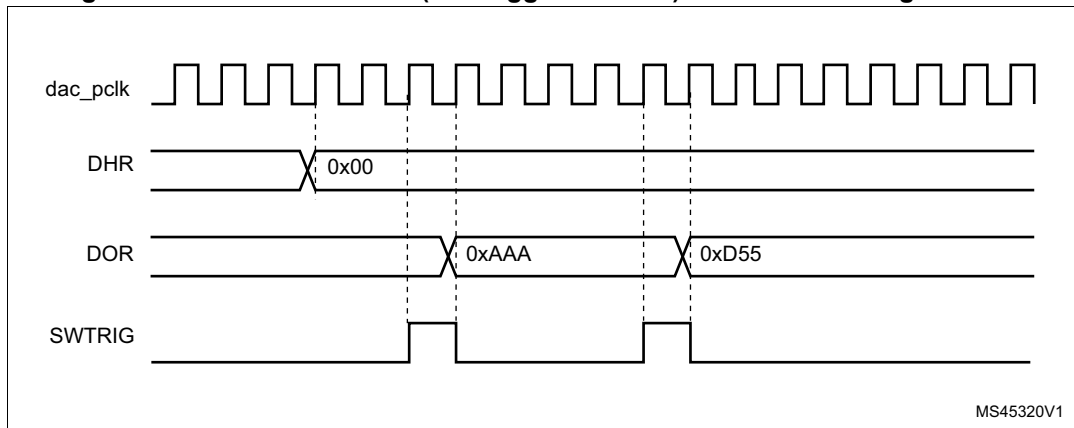

ai14713c

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC\_CR register, is added up to the DAC\_DHRx contents without overflow and this value is then transferred into the DAC\_DORx register.

If LFSR is 0x0000, a '1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

**Figure 199. DAC conversion (SW trigger enabled) with LFSR wave generation**

*Note:* The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC\_CR register.

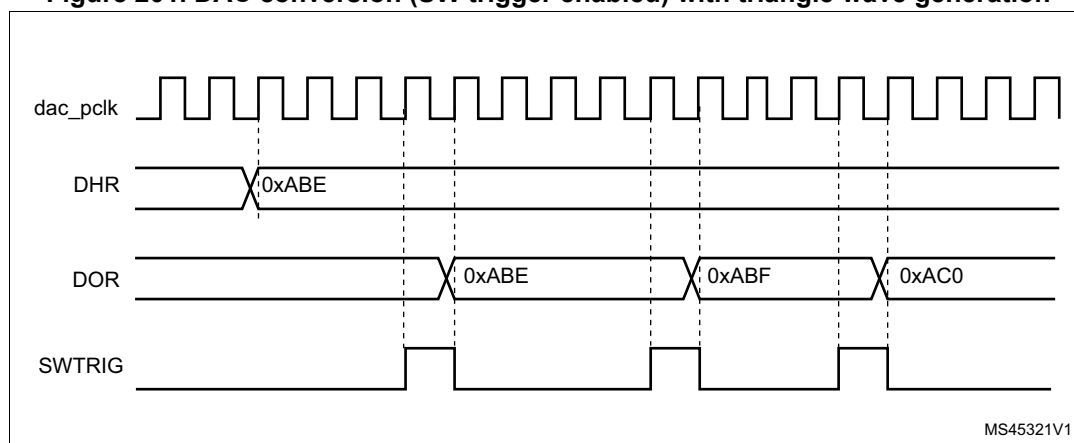

### 26.3.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to "10". The amplitude is configured through the MAMPx[3:0] bits in the DAC\_CR register. An internal triangle counter is incremented three dac\_pclk clock cycles after each trigger event. The value of this counter is then added to the DAC\_DHRx register without overflow and the sum is transferred into the DAC\_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

**Figure 200. DAC triangle wave generation**

**Figure 201. DAC conversion (SW trigger enabled) with triangle wave generation**

**Note:** The DAC trigger must be enabled for noise generation by setting the *TENx* bit in the *DAC\_CR* register.

The *MAMPx[3:0]* bits must be configured before enabling the DAC, otherwise they cannot be changed.

### 26.3.11 DAC channel modes

Each DAC channel can be configured in normal mode or sample and hold mode. The output buffer can be enabled to allow a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

#### Normal mode

In normal mode, there are four combinations, by changing the buffer state and by changing the *DAC\_OUTx* pin interconnections.

To enable the output buffer, the *MODEx[2:0]* bits in *DAC\_MCR* register should be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the *MODEx[2:0]* bits in *DAC\_MCR* register should be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

#### Sample and Hold mode

In sample and Hold mode, the DAC core converts data on a triggered conversion, then, holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A new stabilization period ( $T_{stab-BON}$  or  $T_{stab-BOFF}$  depending on buffer state) is needed before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the low-speed clock (*lsi\_ck*: Low Speed Internal oscillator) in addition to the *dac\_pclk* clock, allowing to use the DAC channels in deep low power modes such as Stop mode.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMx[9:0] bits in DAC\_SHSRx register. During the write of the TSAMx[9:0] bits; the BWSTx bit in DAC\_SR register is set to 1 to synchronize between both clocks domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC\_SHHR register
3. Refresh phase: the refresh time is configured with the TREFx[7:0] bits in DAC\_SHRR register

The timings for the three phases above are in units of lsi\_ck clocks. As example, to configure a Sample time of 350µs, Hold time of 2ms and Refresh time of 100µs assuming lsi\_ck ~32KHz is selected:

12 cycles are required for sample phase: SAMx[9:0] = 11, 62 cycles are required for hold phase: THOLDx[9:0] = 62, and 4 cycles are required for refresh period: TREFx[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The Formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

**Table 210. Sample and refresh timings**

Buffer State	$t_{\text{sampling}} (1)(3)$	$t_{\text{refresh}} (2)(3)$
Enable	$T_{\text{stab-BON}} + (10 \cdot R_{\text{BON}} \cdot C_{\text{load}})$	$T_{\text{stab-BON}} + (R_{\text{BON}} \cdot C_{\text{load}}) \cdot \ln(2 \cdot N_{\text{lsb}})$
Disable	$T_{\text{stab-BOFF}} + (10 \cdot R_{\text{BOFF}} \cdot C_{\text{load}})$	$T_{\text{stab-BOFF}} + (R_{\text{BOFF}} \cdot C_{\text{load}}) \cdot \ln(2 \cdot N_{\text{lsb}})$

*Note:* In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.

The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires  $\ln(2 \cdot N_{\text{lsb}})$  constant time of the DAC.

The parameters  $T_{\text{stab-BON}}$ ,  $T_{\text{stab-BOFF}}$ ,  $R_{\text{BON}}$  and  $R_{\text{BOFF}}$  are specified in the datasheet.

**Example of the sample and refresh time calculation with output buffer on**

*Note:* The values used in the example below are provided as indication only. Please refer to the product datasheet for product data.

$C_{\text{load}} = 100 \text{ nF}$

$V_{\text{DDA}} = 3.0 \text{ V}$

Sampling phase:

$t_{\text{sampling}} = 7 \mu\text{s} + (10 \cdot 2000 \cdot 100 \cdot 10^{-9}) = 2.007 \text{ ms}$   
 (where  $T_{\text{stab-BON}} = 7 \mu\text{s}$ ,  $R_{\text{BON}} = 2 \text{ k}\Omega$ )

Refresh phase:

$$t_{\text{refresh}} = 7 \mu\text{s} + (2000 * 100 * 10^{-9}) * \ln(2*10) = 606.1 \mu\text{s}$$

(where  $N_{\text{lsb}} = 10$  (10 LSB drop during the hold phase))

Hold phase:

$$D_v = i_{\text{leak}} * t_{\text{hold}} / C_{\text{load}} = 0.0073 \text{ V (10 LSB of 12bit at 3 V)}$$

$$i_{\text{leak}} = 150 \text{ nA (worst case on the IO leakage on all the temperature range)}$$

$$t_{\text{hold}} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 \text{ ms}$$

Figure 202. DAC sample and hold mode phase diagram

Like in normal mode, the sample and hold mode has different configurations.

To enable the output buffer, the MODEx[2:0] bits in DAC\_MCR register should be:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, The MODEx[2:0] bits in DAC\_MCR register should be:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits in DAC\_MCR register is equal to 111. An internal capacitor “Cloadint” will hold the voltage output of the DAC Core and then drive it to on-chip peripherals.

All sample and hold phases are interruptible and any change in DAC\_DHRx will trigger immediately a new sample phase.

Table 211. Channel output modes summary

MODEx[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	0	1			Connected to external pin and to on chip-peripherals (ex, comparators)
0	1	0		Disabled	Connected to external pin
0	1	1			Connected to on chip peripherals (ex, comparators)
1	0	0	Sample & hold mode	Enabled	Connected to external pin
1	0	1			Connected to external pin and to on chip peripherals (ex, comparators)
1	1	0		Disabled	Connected to external pin and to on chip peripherals (ex, comparators)
1	1	1			Connected to on chip peripherals (ex, comparators)

### 26.3.12 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = ((D / 2^N - 1) \times G \times V_{ref}) + V_{OS}$$

Where  $V_{OUT}$  is the analog output, D is the digital input, G is the gain,  $V_{ref}$  is the nominal full-scale voltage, and  $V_{os}$  is the offset voltage. For an ideal DAC channel,  $G = 1$  and  $V_{os} = 0$ .

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the  $V_{os}$ , a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output will be disconnected from the pin internal/external connections and put in tristate mode (HiZ),
- The buffer will act as a comparator, to sense the middle-code value 0x800 and compare it to VREF+/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL\_FLAGx bit)

Two calibration techniques are provided:

- Factory trimming (always enabled)

The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC\_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- User trimming

The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when VDD/VDDA voltage, temperature, VREF+ values change and can be done at any point during application by software.

*Note:* Refer to the datasheet for more details of the Nominal factory trimming conditions

Also, when VDD/VDDA is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, Write 0 to ENx bit in DAC\_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DACx\_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b,
3. Start the DAC channelx calibration, by setting the CENx bit in DACx\_CR register to 1,
4. Apply a trimming algorithm:
  - a) Write a code into OTRIMx[4:0] bits, starting by 00000b
  - b) Wait for  $t_{OFFTRIMmax}$  delay
  - c) Check if CAL\_FLAGx bit in DACx\_SR is set to 1
  - d) if CAL\_FLAGx is set to 1 the trimming code OTRIMx[4:0] is found and will be used during operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way,

The commutation/toggle of CAL\_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC\_CCR register.

*Note:* A  $t_{OFFTRIMmax}$  delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL\_FLAGx bit in DAC\_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

*If the VDD/VDDA, VREF+ and temperature conditions will not change during the device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.*

### 26.3.13 Dual DAC channel conversion (if available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time.

Eleven possible conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

#### Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[3:0] and TSEL2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC\_DOR1 (three dac\_pclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC\_DOR2 (three `dac_pclk` clock cycles later).

### Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three `dac_pclk` clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three `dac_pclk` clock cycles later). Then the LFSR2 counter is updated.

### Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR mask values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three `dac_pclk` clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three `dac_pclk` clock cycles later). Then the LFSR2 counter is updated.

### Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three dac\_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three dac\_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

### Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three dac\_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three dac\_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

### Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

In this configuration, one dac\_pclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively.

### Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[3:0] and TSEL2[3:0] bits
- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively (after three dac\_pclk clock cycles).

### Simultaneous trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three dac\_pclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three dac\_pclk clock cycles later). The LFSR2 counter is then updated.

### Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three dac\_pclk clock cycles later). The LFSR1 counter is then updated.

At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three dac\_pclk clock cycles later). The LFSR2 counter is then updated.

### Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value using the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three dac\_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three dac\_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

### Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[3:0] and TSEL2[3:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three dac\_pclk clock cycles later). Then the DAC channel2 triangle counter is updated.

## 26.4 DAC low-power modes

Table 212. Effect of low-power modes on DAC

Mode	Description
Sleep	No effect, DAC can be used with DMA
Stop	DAC remains active with a static output value if sample and hold mode is selected using lsi_ck clock
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby mode.

## 26.5 DAC registers

Refer to [Section 1 on page 98](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

### 26.5.1 DAC control register (DAC\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CEN2	DMAU DRIE2	DMA EN2	MAMP2[3:0]				WAVE2[1:0]		TSEL2 3	TSEL2 2	TSEL2 1	TSEL2 0	TEN2	EN2
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CEN1	DMAU DRIE1	DMA EN1	MAMP1[3:0]				WAVE1[1:0]		TSEL1 3	TSEL1 2	TSEL1 1	TSEL1 0	TEN1	EN1
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value

Bit 30 **CEN2**: DAC Channel 2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel 2 calibration, it can be written only if bit EN2=0 into DAC\_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

- 0: DAC channel 2 in normal operating mode
- 1: DAC channel 2 in calibration mode

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

- 0: DAC channel2 DMA underrun interrupt disabled
- 1: DAC channel2 DMA underrun interrupt enabled

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

- 0: DAC channel2 DMA mode disabled
- 1: DAC channel2 DMA mode enabled

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
 ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled  
 01: Noise wave generation enabled  
 1x: Triangle wave generation enabled

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)*

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

0000: Software trigger  
 0001: TIM1\_TRGO  
 0010: TIM2\_TRGO  
 0011: TIM4\_TRGO  
 0100: TIM5\_TRGO  
 0101: TIM6\_TRGO  
 0110: TIM7\_TRGO  
 0111: TIM8\_TRGO  
 1000: TIM15\_TRGO  
 1001: HRTIM1\_DACTRG1  
 1010: HRTIM1\_DACTRG2  
 1011: LPTIM1\_OUT  
 1100: LPTIM2\_OUT  
 1101: EXTI9  
 1110: Reserved  
 1111: Reserved

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).*

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC\_DHRx register are transferred one *dac\_pclk* clock cycle later to the DAC\_DOR2 register

1: DAC channel2 trigger enabled and data from the DAC\_DHRx register are transferred three *dac\_pclk* clock cycles later to the DAC\_DOR2 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR2 register takes only one *dac\_pclk* clock cycle.*

- Bit 16 **EN2**: DAC channel2 enable  
This bit is set and cleared by software to enable/disable DAC channel2.  
0: DAC channel2 disabled  
1: DAC channel2 enabled
- Bit 15 Reserved, must be kept at reset value.
- Bit 14 **CEN1**: DAC Channel 1 calibration enable  
This bit is set and cleared by software to enable/disable DAC channel 1 calibration, it can be written only if bit EN1=0 into DAC\_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.  
0: DAC channel 1 in normal operating mode  
1: DAC channel 1 in calibration mode
- Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable  
This bit is set and cleared by software.  
0: DAC channel1 DMA Underrun Interrupt disabled  
1: DAC channel1 DMA Underrun Interrupt enabled
- Bit 12 **DMAEN1**: DAC channel1 DMA enable  
This bit is set and cleared by software.  
0: DAC channel1 DMA mode disabled  
1: DAC channel1 DMA mode enabled
- Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector  
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.  
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095
- Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable  
These bits are set and cleared by software.  
00: wave generation disabled  
01: Noise wave generation enabled  
1x: Triangle wave generation enabled  
*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bits 5:2 **TSEL1[3:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1

- 0000: Software trigger
- 0001: TIM1\_TRGO
- 0010: TIM2\_TRGO
- 0011: TIM4\_TRGO
- 0100: TIM5\_TRGO
- 0101: TIM6\_TRGO
- 0110: TIM7\_TRGO
- 0111: TIM8\_TRGO
- 1000: TIM15\_TRGO
- 1001: HRTIM1\_DACTRG1
- 1010: HRTIM1\_DACTRG2
- 1011: LPTIM1\_OUT
- 1100: LPTIM2\_OUT
- 1101: EXTI9
- 1110: Reserved
- 1111: Reserved

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bit 1 **TEN1**: DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

0: DAC channel1 trigger disabled and data written into the DAC\_DHRx register are transferred one *dac\_pclk* clock cycle later to the DAC\_DOR1 register

1: DAC channel1 trigger enabled and data from the DAC\_DHRx register are transferred three *dac\_pclk* clock cycles later to the DAC\_DOR1 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR1 register takes only one dac\_pclk clock cycle.*

Bit 0 **EN1**: DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.

- 0: DAC channel1 disabled
- 1: DAC channel1 enabled

### 26.5.2 DAC software trigger register (DAC\_SWTRGR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWTRIG2	SWTRIG1
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

*Note: This bit is cleared by hardware (one dac\_pclk clock cycle later) once the DAC\_DHR2 register value has been loaded into the DAC\_DOR2 register.*

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

*Note: This bit is cleared by hardware (one dac\_pclk clock cycle later) once the DAC\_DHR1 register value has been loaded into the DAC\_DOR1 register.*

### 26.5.3 DAC channel1 12-bit right-aligned data holding register (DAC\_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	DACD1DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

### 26.5.4 DAC channel1 12-bit left aligned data holding register (DAC\_DHR12L1)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

DACD1DHR[11:0]												Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

### 26.5.5 DAC channel1 8-bit right aligned data holding register (DAC\_DHR8R1)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DACC1DHR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel1.

### 26.5.6 DAC channel2 12-bit right aligned data holding register (DAC\_DHR12R2)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC2DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel2.

### 26.5.7 DAC channel2 12-bit left aligned data holding register (DAC\_DHR12L2)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
DACC2DHR[11:0]												Res.	Res.	Res.	Res.	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data

These bits are written by software which specify 12-bit data for DAC channel2.

Bits 3:0 Reserved, must be kept at reset value.

### 26.5.8 DAC channel2 8-bit right-aligned data holding register (DAC\_DHR8R2)

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DACC2DHR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel2.

### 26.5.9 Dual DAC 12-bit right-aligned data holding register (DAC\_DHR12RD)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	DACC2DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	DACC1DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

### 26.5.10 DUAL DAC 12-bit left aligned data holding register (DAC\_DHR12LD)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DACC2DHR[11:0]												Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DACC1DHR[11:0]												Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:20 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data  
 These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data  
 These bits are written by software which specifies 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

### 26.5.11 DUAL DAC 8-bit right aligned data holding register (DAC\_DHR8RD)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DACC2DHR[7:0]								DACC1DHR[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data  
 These bits are written by software which specifies 8-bit data for DAC channel2.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data  
 These bits are written by software which specifies 8-bit data for DAC channel1.

### 26.5.12 DAC channel1 data output register (DAC\_DOR1)

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	DACC1DOR[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DOR[11:0]**: DAC channel1 data output

These bits are read-only, they contain data output for DAC channel1.

### 26.5.13 DAC channel2 data output register (DAC\_DOR2)

Address offset: 0x30

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	DACC2DOR[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DOR[11:0]**: DAC channel2 data output

These bits are read-only, they contain data output for DAC channel2.

### 26.5.14 DAC status register (DAC\_SR)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWST2	CAL_FLAG2	DMAU DR2	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	rc_w1													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BWST1	CAL_FLAG1	DMAU DR1	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	rc_w1													

Bit 31 **BWST2**: DAC Channel 2 busy writing sample time flag  
 This bit is systematically set just after Sample & Hold mode enable and is set each time the software writes the register DAC\_SHSR2, It is cleared by hardware when the write operation of DAC\_SHSR2 is complete. (It takes about 3 lsi\_ck periods of synchronization).  
 0: There is no write operation of DAC\_SHSR2 ongoing: DAC\_SHSR2 can be written  
 1: There is a write operation of DAC\_SHSR2 ongoing: DAC\_SHSR2 cannot be written

Bit 30 **CAL\_FLAG2**: DAC Channel 2 calibration offset status  
 This bit is set and cleared by hardware  
 0: calibration trimming value is lower than the offset correction value  
 1: calibration trimming value is equal or greater than the offset correction value

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag  
 This bit is set by hardware and cleared by software (by writing it to 1).  
 0: No DMA underrun error condition occurred for DAC channel2  
 1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate)

Bits 28:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC Channel 1 busy writing sample time flag  
 This bit is systematically set just after Sample & Hold mode enable and is set each time the software writes the register DAC\_SHSR1, It is cleared by hardware when the write operation of DAC\_SHSR1 is complete. (It takes about 3 lsi\_ck periods of synchronization).  
 0: There is no write operation of DAC\_SHSR1 ongoing: DAC\_SHSR1 can be written  
 1: There is a write operation of DAC\_SHSR1 ongoing: DAC\_SHSR1 cannot be written

Bit 14 **CAL\_FLAG1**: DAC Channel 1 calibration offset status  
 This bit is set and cleared by hardware  
 0: calibration trimming value is lower than the offset correction value  
 1: calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag  
 This bit is set by hardware and cleared by software (by writing it to 1).  
 0: No DMA underrun error condition occurred for DAC channel1  
 1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bits 12:0 Reserved, must be kept at reset value.

### 26.5.15 DAC calibration control register (DAC\_CCR)

Address offset: 0x38

Reset value: 0x00XX 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM2[4:0]				
											rw				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OTRIM1[4:0]				
											rw				

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 OTRIM2[4:0]: DAC Channel 2 offset trimming value

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 OTRIM1[4:0]: DAC Channel 1 offset trimming value

**26.5.16 DAC mode control register (DAC\_MCR)**

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE2[2:0]	
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MODE1[2:0]	
															rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE2[2:0]**: DAC Channel 2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2=0 and bit CEN2 =0 in the DAC\_CR register). If EN2=1 or CEN2 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC Channel 2 mode:

- DAC Channel 2 in normal Mode
  - 000: DAC Channel 2 is connected to external pin with Buffer enabled
  - 001: DAC Channel 2 is connected to external pin and to on chip peripherals with buffer enabled
  - 010: DAC Channel 2 is connected to external pin with buffer disabled
  - 011: DAC Channel 2 is connected to on chip peripherals with Buffer disabled
- DAC Channel 2 in sample & hold mode
  - 100: DAC Channel 2 is connected to external pin with Buffer enabled
  - 101: DAC Channel 2 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC Channel 2 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC Channel 2 is connected to on chip peripherals with Buffer disabled

Bits 15:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]**: DAC Channel 1 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1=0 and bit CEN1 =0 in the DAC\_CR register). If EN1=1 or CEN1 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC Channel 1 mode:

- DAC Channel 1 in normal Mode
  - 000: DAC Channel 1 is connected to external pin with Buffer enabled
  - 001: DAC Channel 1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 010: DAC Channel 1 is connected to external pin with Buffer disabled
  - 011: DAC Channel 1 is connected to on chip peripherals with Buffer disabled
- DAC Channel 1 in sample & hold mode
  - 100: DAC Channel 1 is connected to external pin with Buffer enabled
  - 101: DAC Channel 1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC Channel 1 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC Channel 1 is connected to on chip peripherals with Buffer disabled

### 26.5.17 DAC Sample and Hold sample time register 1 (DAC\_SHSR1)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16						
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.						
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE1[9:0]									rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]**: DAC Channel 1 sample Time (only valid in sample & hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. in the latter case, the write can be done only when BWSTx of DAC\_SR register is low, If BWSTx=1, the write operation is ignored.

*Note:* It represents the number of lsi\_ck clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x T lsi\_ck.

### 26.5.18 DAC Sample and Hold sample time register 2 (DAC\_SHSR2)

Address offset: 0x44

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE2[9:0]									Res.	Res.
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE2[9:0]**: DAC Channel 2 sample Time (only valid in sample & hold mode)

These bits can be written when the DAC channel2 is disabled or also during normal operation. in the latter case, the write can be done only when BWSTx of DAC\_SR register is low, if BWSTx=1, the write operation is ignored.

*Note:* It represents the number of lsi\_ck clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x T lsi\_ck.

### 26.5.19 DAC Sample and Hold hold time register (DAC\_SHHR)

Address offset: 0x48

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Res.	Res.	Res.	Res.	Res.	Res.	THOLD2[9:0]									Res.	Res.
						rw										
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Res.	Res.	Res.	Res.	Res.	Res.	THOLD1[9:0]									Res.	Res.
						rw										

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **THOLD2[9:0]**: DAC Channel 2 hold time (only valid in sample & hold mode).

$$\text{Hold time} = (\text{THOLD}[9:0]) \times T_{\text{Isi\_ck}}$$

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **THOLD1[9:0]**: DAC Channel 1 hold Time (only valid in sample & hold mode)

$$\text{Hold time} = (\text{THOLD}[9:0]) \times T_{\text{Isi\_ck}}$$

*Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit ENx=0 and bit CEN2x=0 in the DAC\_CR register). If ENx=1 or CENx=1 the write operation is ignored.*

### 26.5.20 DAC Sample and Hold refresh time register (DAC\_SHRR)

Address offset: 0x4C

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH2[7:0]							
								rw							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH1[7:0]							
								rw							

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TREFRESH2[7:0]**: DAC Channel 2 refresh Time (only valid in sample & hold mode)

$$\text{Refresh time} = (\text{TREFRESH}[7:0]) \times T_{\text{Isi\_ck}}$$

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **TREFRESH1[7:0]**: DAC Channel 1 refresh Time (only valid in sample & hold mode)

$$\text{Refresh time} = (\text{TREFRESH}[7:0]) \times T_{\text{Isi\_ck}}$$

*Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit ENx=0 and bit CEN2x=0 in the DAC\_CR register). If ENx=1 or CENx=1 the write operation is ignored.*

**26.5.21 DAC option register (DAC\_OR)**

## 27 Voltage reference buffer (VREFBUF)

### 27.1 Introduction

The STM32H7x3 devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin.

### 27.2 VREFBUF functional description

The internal voltage reference buffer supports five voltages, which are configured with VRS bit in the VREF\_CSR register:

- VRS=000: around 2.5 V. This requires  $V_{DDA}$  equal to or higher than 2.8 V.
- VRS=001: around 2.048 V. This requires  $V_{DDA}$  equal to or higher than 2.4 V.
- VRS=010: around 1.8 V. This requires  $V_{DDA}$  equal to or higher than 2.1 V.
- VRS=011: around 1.5 V. This requires  $V_{DDA}$  equal to or higher than 1.8 V.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

**Table 214. VREF buffer modes**

ENVR	HIZ	VREF buffer configuration
0	0	VREFBUF OFF: – VREF+ pin pulled-down to $V_{SSA}$
0	1	External voltage reference mode (default value): – VREFBUF OFF – VREF+ pin input mode
1	0	Internal voltage reference mode: – VREFBUF ON – VREF+ pin connected to VREFBUF output
1	1	Hold mode: – VREFBUF OFF – VREF+ pin floating. The voltage is held with the external capacitor

After enabling the VREFBUF by setting ENVR bit in the VREFBUF\_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

## 27.3 VREFBUF registers

### 27.3.1 VREFBUF control and status register (VREFBUF\_CSR)

Address offset: 0x00

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res	Res	Res	Res	Res	Res	Res	Res	Res	VRS[2:0]			VRR	Res	HIZ	ENVR
									rw	rw	rw	r		rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

000: Voltage reference set to 2.5 V

001: Voltage reference set to 2.048 V

010: Voltage reference set to 1.8 V

011: Voltage reference set to 1.5 V

Other: Reserved

Bit 3 **VRR**: Voltage reference buffer ready

0: the voltage reference buffer output is not ready.

1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ**: High impedance mode

This bit controls the analog switch to connect or not the  $V_{REF+}$  pin.

0:  $V_{REF+}$  pin is internally connected to the voltage reference buffer output.

1:  $V_{REF+}$  pin is high impedance.

Refer to [Table 214: VREF buffer modes](#) for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR**: Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.

0: Internal voltage reference mode disable (external voltage reference mode).

1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

### 27.3.2 VREFBUF calibration control register (VREFBUF\_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	Res
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res	Res	Res	Res	Res	Res	Res	Res	Res	Res	TRIM[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]**: Trimming code

These bits are automatically initialized after reset with the trimming value stored in the Flash memory during the production test. Writing into these bits allows to tune the internal reference buffer voltage.

### 27.3.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

**Table 215. VREFBUF register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0x04	VREFBUF_CCR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRIM[5:0]									
	Reset value																												x	x	x	x	x	x			

Refer to [Section 2.2.2 on page 105](#) for the register boundary addresses.

## 28 Comparator (COMP)

### 28.1 Introduction

The device embeds two ultra-low-power comparator channels (COMP1 and COMP2). They can be used for a variety of functions including:

- wake up from low-power mode triggered by an analog signal
- analog signal conditioning
- cycle-by-cycle current control loop when combined with a PWM output from a timer

### 28.2 COMP main features

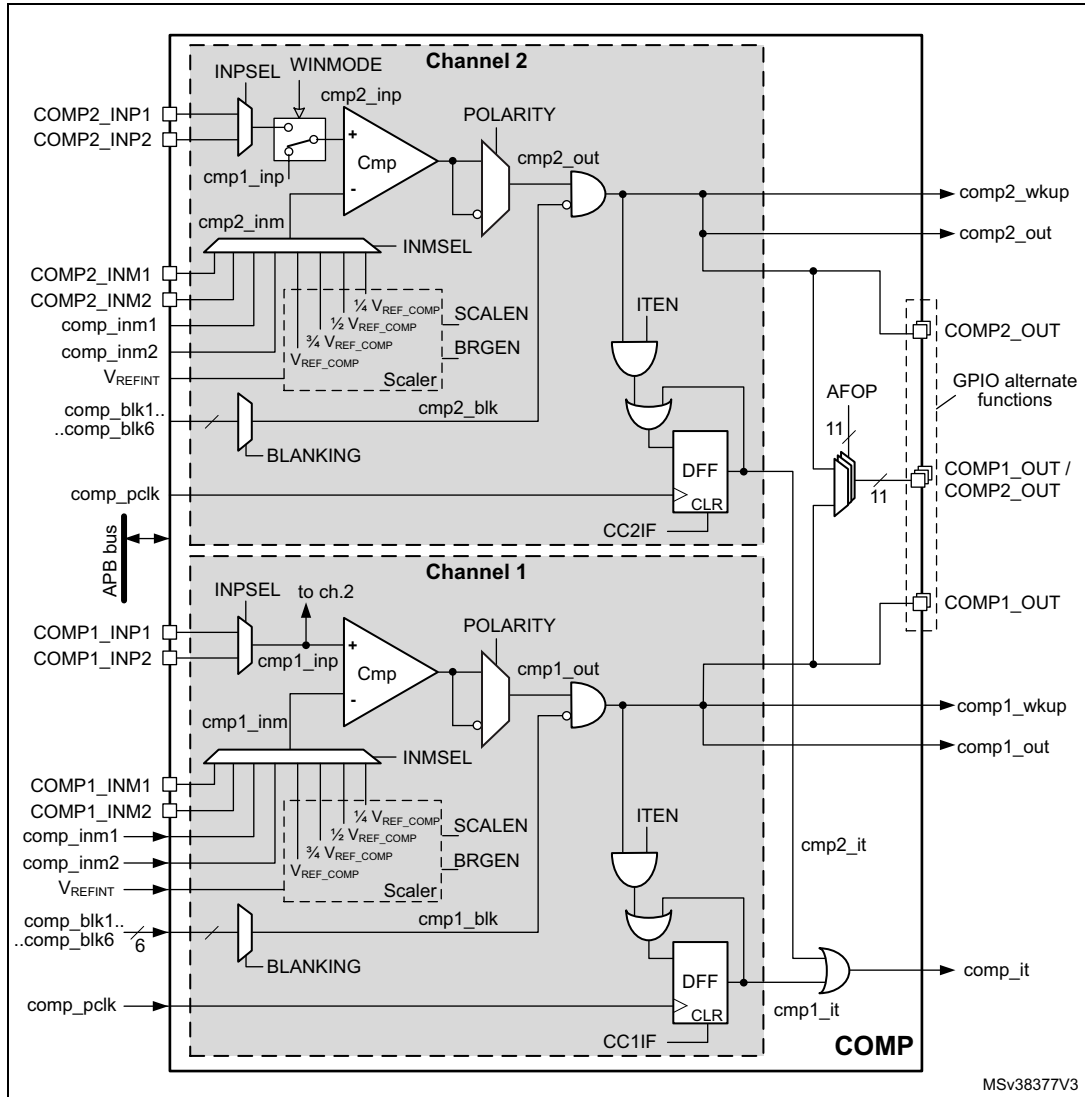

- Selectable inverting analog inputs:
  - I/O pins (different for either channel)
  - DAC Channel1 and Channel2 outputs
  - internal reference voltage and three sub multiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Two I/O pins per channel selectable as non-inverting analog inputs
- Programmable hysteresis
- Programmable speed / consumption
- Mapping of outputs to I/Os
- Redirection of outputs to timer inputs for triggering:
  - capture events
  - OCREF\_CLR events (for cycle-by-cycle current control)
  - break events for fast PWM shutdowns
- Blanking of comparator outputs
- Window comparator
- Interrupt generation capability with wake up from Sleep and Stop modes (through the EXTI controller)
- Direct interrupt output to the CPU

## 28.3 COMP functional description

### 28.3.1 COMP block diagram

The block diagram of the comparators is shown in [Figure 203: Comparator functional block diagram](#).

Figure 203. Comparator functional block diagram

### 28.3.2 COMP pins and internal signals

The I/Os used as comparator inputs must be configured in analog mode in the GPIO registers.

The comparator outputs can be connected to the I/Os through their alternate functions. Refer to the product datasheet.

The outputs can also be internally redirected to a variety of timer inputs for the following purposes:

- emergency shut-down of PWM signals, using BKIN and BKIN2 inputs
- cycle-by-cycle current control, using ETR inputs of timers
- input capture for timing measurements

The comparator output can be routed simultaneously internally and to the I/O pins.

**Table 216. COMP input/output internal signals**

Signal name	Signal type	Description
comp_inm1	Analog input	Inverting input source for both COMP channels: DAC ch.1
comp_inm2	Analog input	Inverting input source for both COMP channels: DAC ch.2
comp_blk1	Digital input	Blanking input source for both COMP channels: TIM1 OC5
comp_blk2	Digital input	Blanking input source for both COMP channels: TIM2 OC3
comp_blk3	Digital input	Blanking input source for both COMP channels: TIM3 OC3
comp_blk4	Digital input	Blanking input source for both COMP channels: TIM3 OC4
comp_blk5	Digital input	Blanking input source for both COMP channels: TIM8 OC5
comp_blk6	Digital input	Blanking input source for both COMP channels: TIM15 OC1
comp_pclk	Digital input	APB clock for both COMP channels
comp1_wkup	Digital output	COMP channel 1 wakeup out
comp1_out	Digital output	COMP channel 1 out
comp2_wkup	Digital output	COMP channel 2 wakeup out
comp2_out	Digital output	COMP channel 2 out
comp_it	Digital output	COMP interrupt out

**Table 217. COMP input/output pins**

Signal name	Signal type	Description
COMP1_INM1	Analog input	COMP channel 1 inverting input source 1 (PB1)
COMP1_INM2	Analog input	COMP channel 1 inverting input source 2 (PC4)
COMP1_INP1	Analog input	COMP channel 1 non-inverting input source 1 (PB0)
COMP1_INP2	Analog input	COMP channel 1 non-inverting input source 2 (PB2)
COMP2_INM1	Analog input	COMP channel 2 inverting input source 1 (PE10)
COMP2_INM2	Analog input	COMP channel 2 inverting input source 2 (PE7)
COMP2_INP1	Analog input	COMP channel 2 non-inverting input source 1 (PE9)
COMP2_INP2	Analog input	COMP channel 2 non-inverting input source 2 (PE11)
COMP1_OUT	Digital output	COMP channel 1 output: see <a href="#">Section 28.3.8: Comparator output on GPIOs</a> .
COMP2_OUT	Digital output	COMP channel 2 output: see <a href="#">Section 28.3.8: Comparator output on GPIOs</a> .

### 28.3.3 COMP reset and clocks

The clock `comp_pclk` provided by the clock controller is synchronous with the APB clock.

*Note:* **Important:** *The polarity selection logic and the output redirection to the port works independently from the APB clock. This allows the comparator to work even in Stop mode. The interrupt line, connected to the NVIC of CPU, requires the APB clock (`comp_pclk`) to work. In absence of the APB clock, the interrupt signal `comp_it` cannot be generated.*

### 28.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications with specific functional safety requirements, the comparator configuration can be protected against undesired alteration that could happen, for example, at program counter corruption.

For this purpose, the comparator configuration registers can be write-protected (read-only).

Upon configuring a comparator channel, its LOCK bit is set to 1. This causes the whole register set of the comparator channel, as well as the common COMP\_OR register, to become read-only, the LOCK bit inclusive.

The write protection can only be removed through the MCU reset.

The COMP\_OR register is locked by the LOCK bit of COMP\_CFGR1 OR COMP\_CFGR2.

### 28.3.5 Window comparator

The purpose of the window comparator is to monitor the analog voltage and check that it is comprised within the specified voltage range defined by lower and upper thresholds.

The window comparator requires both COMP channels. The monitored analog voltage is connected to their non-inverting (plus) inputs and the upper and lower threshold voltages are connected to the inverting (minus) input of either comparator, respectively. The non-inverting input of the COMP channel 2 can be connected internally with the non-inverting input of the COMP channel 1 by enabling WINMODE bit. This can save the input pins of COMP channel 2 for other purposes. See [Figure 203: Comparator functional block diagram](#).

### 28.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.

Figure 204. Comparator hysteresis

MS19984V1

### 28.3.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It uses a blanking window defined with a timer output compare signal. Refer to the register description for selectable blanking signals. The blanking signal gates the internal comparator output such as to clean the comp\_out from spurious pulses due to current spikes, as depicted in [Figure 205](#) (the COMP channel number is not represented).

Figure 205. Comparator output blanking

MS30964V2

### 28.3.8 Comparator output on GPIOs

The COMP1\_OUT and COMP2\_OUT outputs of the comparator channels are mapped to GPIOs through the AFOP field of the COMP\_OR register, bits [10:0], and through the GPIO alternate function.

**Table 218. COMP1\_OUT assignment to GPIOs**

COMP1_OUT	Alternate Function
PC5	AF13
PE12	AF13
PA6	AF10, AF12 (can be used as timer break in)
PA8	AF12 (can be used as timer break in)
PB12	AF13 (can be used as timer break in)
PE6	AF11 (can be used as timer break in)
PE15	AF13 (can be used as timer break in)
PG2	AF11 (can be used as timer break in)
PG3	AF11 (can be used as timer break in)
PG4	AF11 (can be used as timer break in)
PI1	AF11 (can be used as timer break in)
PI4	AF11 (can be used as timer break in)
PK2	AF10, AF11 (can be used as timer break in)

**Table 219. COMP2\_OUT assignment to GPIOs**

COMP2_OUT	Alternate Function
PE8	AF13
PE13	AF13
PA6	AF10, AF12 (can be used as timer break in)
PA8	AF12 (can be used as timer break in)
PB12	AF13 (can be used as timer break in)
PE6	AF11 (can be used as timer break in)
PE15	AF13 (can be used as timer break in)
PG2	AF11 (can be used as timer break in)
PG3	AF11 (can be used as timer break in)
PG4	AF11 (can be used as timer break in)
PI1	AF11 (can be used as timer break in)
PI4	AF11 (can be used as timer break in)
PK2	AF10, AF11 (can be used as timer break in)

The assignment to GPIOs for both comparator channel outputs must be done before locking registers of any channel, because the common COMP\_OR register is locked when locking the registers of either comparator channel.

### 28.3.9 Comparator output redirection

The outputs of either COMP channel can be redirected to timer break inputs (TIMx\_BKIN or TIMx\_BKIN2), as shown in [Figure 206](#). For that end, the COMP channel output is connected to one of GPIOs programmable in alternate function as timer break input. See [Table 218](#) and [Table 219](#). The selected GPIO(s) must be set in open drain mode. The COMP output passes through the GPIO to the timer break input. With a pull-up resistor, the selected GPIO can be used as timer break input logic OR-ed with the comparator output.

**Figure 206. Output redirection**

### 28.3.10 COMP power and speed modes

The power consumption of the COMP channels versus propagation delay can be adjusted to have the optimum trade-off for a given application.

The bits PWRMODE[1:0] in COMP\_CFGRx registers can be programmed as follows:

- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Medium speed / medium power
- 11: Very-low speed / ultra-low-power

## 28.4 COMP low-power modes

**Table 220. Comparator behavior in the low-power modes**

Mode	Description
Sleep	No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.
Stop	No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.

*Note:* The comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off.

## 28.5 COMP interrupts

There are two ways to use the comparator as interrupt source.

The comparator outputs are internally connected to the Extended interrupt and event controller. Each comparator has its own EXTI line and can generate either interrupts or events to make the device exit low-power modes.

The comparators also provide an interrupt line to the NVIC of CPU. This functionality is used when the CPU is active to handle low latency interrupt. It requires APB clock running.

### 28.5.1 Interrupt through EXTI block

Refer to Interrupt and events section for more details.

Sequence to enable the COMPx interrupt through EXTI block:

1. Configure the EXTI line, receiving the comp\_wkup signal, in interrupt mode, select the rising, falling or either-edge sensitivity and enable the EXTI line.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

**Table 221. Interrupt control bits**

Interrupt event	Event flag	Enable control bit	Exit from Sleep mode	Exit from Stop modes	Exit from Standby mode
comp1_wkup	through EXTI	through EXTI	yes	yes	N/A
comp2_wkup	through EXTI	through EXTI	yes	yes	N/A

### 28.5.2 Interrupt through NVIC of the CPU

Sequence to enable the COMPx interrupt through NVIC of the CPU:

1. Configure and enable the NVIC IRQ channel mapped to the comp\_it line.
2. Configure and enable the ITEN in COMP\_CFGRx.
3. Enable the COMPx.

Table 222. Interrupt control bits

Interrupt event	Interrupt flag	Enable control bit	Interrupt clear bit	Exit from Sleep mode	Exit from Stop modes
comp_it	C1IF in	ITEN in COMP_CFGR1	CC1IF	yes (With APB clock)	no
comp_it	C2IF in	ITEN in COMP_CFGR2	CC2IF	yes (With APB clock)	no

Note: It is mandatory to enable APB clock to use this interrupt. If clock is not enabled, interrupt is not generated.

### 28.6 SCALER function

The scaler block is available to provide the different voltage reference levels to the comparator inputs. It is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference.

The amplifier and the resistor bridge can be enabled separately. The amplifier is enabled by the SCALEN bits of the COMP\_CFGRx registers. The resistor bridge is enabled by the BRGEN bits of the COMP\_CFGRx registers.

When the resistor divided voltage is not used, the resistor bridge can be disconnected in order to reduce the consumption. When it is disconnected, the  $1/4 V_{REF\_COMP}$ ,  $1/2 V_{REF\_COMP}$  and  $3/4 V_{REF\_COMP}$  levels are equal to  $V_{REF\_COMP}$ .

Figure 207. Scaler block diagram

MSv38379V1

## 28.7 COMP registers

### 28.7.1 Comparator status register (COMP\_SR)

The COMP\_SR is the comparator status register.

Address offset: 0x00

System reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	C2IF	C1IF
														r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	C2VAL	C1VAL
														r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **C2IF**: COMP channel 2 Interrupt Flag

This bit is set by hardware when the COMP channel 2 output is set

This bit is cleared by software writing 1 the CC2IF bit in the COMP\_ICFR register.

Bit 16 **C1IF**: COMP channel 1 Interrupt Flag

This bit is set by hardware when the COMP channel 1 output is set

This bit is cleared by software writing 1 the CC1IF bit in the COMP\_ICFR register.

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **C2VAL**: COMP channel 2 output status bit

This bit is read-only. It reflects the current COMP channel 2 output taking into account POLARITY and BLANKING bits effect.

Bit 0 **C1VAL**: COMP channel 1 output status bit

This bit is read-only. It reflects the current COMP channel 1 output taking into account POLARITY and BLANKING bits effect.

### 28.7.2 Comparator interrupt clear flag register (COMP\_ICFR)

The COMP\_ICFR is the Comparator interrupt clear flag register.

Address offset: 0x00

System reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CC2IF	CC1IF
														w1o	w1o
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **CC2IF**: Clear COMP channel 2 Interrupt Flag  
 Writing 1 clears the C2IF flag in the COMP\_SR register.

Bit 16 **CC1IF**: Clear COMP channel 1 Interrupt Flag  
 Writing 1 clears the C1IF flag in the COMP\_SR register.

Bits 15:0 Reserved, must be kept at reset value.

### 28.7.3 Comparator option register (COMP\_OR)

The COMP\_OR is the Comparator option register.

Address offset: 0x08

System reset value: 0x0000 0000

When OR\_CFG=0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OR15	OR14	OR13	OR12	OR11	AFOP										
r/w	r/w	r/w	r/w	r/w	r/w										

When OR\_CFG=1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OR31	OR30	OR29	OR28	OR27	OR26	OR25	OR24	OR23	OR22	OR21	OR20	OR19	OR18	OR17	OR16
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OR15	OR14	OR13	OR12	OR11	AFOP										
r/w	r/w	r/w	r/w	r/w	r/w										

Bits 31:11 **OR**: Option Register (When OR\_CFG=1)

Bits 15:11 **OR**: Option Register (When OR\_CFG=0)

Bits 10:0 **AFOP[10:0]**: Selection of source for alternate function of output ports

Bits of this field are set and cleared by software (only if LOCK not set).

Output port (GPIO) correspondence:

bit 10 bit 9 bit 8 bit 7 bit 6 bit 5 bit 4 bit 3 bit 2 bit 1 bit 0  
 PK2 PI4 PI1 PG4 PG3 PG2 PE15 PE6 PB12 PA8 PA6

For each bit:

0: COMP1\_OUT is selected for the alternate function of the corresponding GPIO

1: COMP2\_OUT is selected for the alternate function of the corresponding GPIO

### 28.7.4 Comparator configuration register 1 (COMP\_CFGR1)

The COMP\_CFGR1 is the COMP channel 1 configuration register.

Address offset: 0x0C

System reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	BLANKING[3:0]				Res.	Res.	Res.	INPSEL	Res.	INMSEL[2:0]		
rw				rw							rw		rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	PWRMODE[1:0]		Res.	Res.	HYST[1:0]		Res.	ITEN	Res.	Res.	POLARITY	SCALEN	BRGEN	EN
		rw				rw			rw			rw	rw	rw	rw

Bit 31 **LOCK**: Lock bit

This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 1 configuration register COMP\_CFGR1[31:0], and COMP\_OR register  
 0: COMP\_CFGR1[31:0] register is read/write  
 1: COMP\_CFGR1[31:0] and COMP\_OR registers are read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **BLANKING[3:0]**: COMP channel 1 blanking source selection bits

Bits of this field are set and cleared by software (only if LOCK not set).  
 The field selects the input source for COMP channel 1 output blanking:  
 0000: No blanking  
 0001: comp\_blk1  
 0010: comp\_blk2  
 0011: comp\_blk3  
 0100: comp\_blk4  
 0101: comp\_blk5  
 0110: comp\_blk6  
 All other values: reserved

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **INPSEL**: COMP channel 1 non-inverting input selection bit

This bit is set and cleared by software (only if LOCK not set).  
 0: COMP1\_INP1 (PB0)  
 1: COMP1\_INP2 (PB2)

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **INMSEL[2:0]**: COMP channel 1 inverting input selection field

These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 1.  
 000 = 1/4 V<sub>REF\_COMP</sub>  
 001 = 1/2 V<sub>REF\_COMP</sub>  
 010 = 3/4 V<sub>REF\_COMP</sub>  
 011 = V<sub>REF\_COMP</sub>  
 100 = comp\_inm1 (DAC channel 1 output)  
 101 = comp\_inm2 (DAC channel 2 output)  
 110 = COMP1\_INM1 (PB1)  
 111 = COMP1\_INM2 (PC4)

Bits 15:14 Reserved, must be kept at reset value.

- Bits 13:12 **PWRMODE[1:0]**: Power Mode of the COMP channel 1  
 These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 1.  
 00: High speed / full power  
 01: Medium speed / medium power  
 10: Medium speed / medium power  
 11: Ultra low power / ultra-low-power
- Bits 11:10 Reserved, must be kept at reset value.
- Bits 9:8 **HYST[1:0]**: COMP channel 1 hysteresis selection bits  
 These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 1.  
 00: No hysteresis  
 01: Low hysteresis  
 10: Medium hysteresis  
 11: High hysteresis
- Bit 7 Reserved, must be kept at reset value.
- Bit 6 **ITEN**: COMP channel 1 interrupt enable  
 This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 1.  
 0: Interrupt generation disabled for COMP channel 1  
 1: Interrupt generation enabled for COMP channel 1
- Bits 5:4 Reserved, must be kept at reset value.
- Bit 3 **POLARITY**: COMP channel 1 polarity selection bit  
 This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 1 polarity.  
 0: COMP channel 1 output is not inverted  
 1: COMP channel 1 output is inverted
- Bit 2 **SCALEN**: Voltage scaler enable bit  
 This bit is set and cleared by software (only if LOCK not set). This bit enables the  $V_{REFINT}$  scaler for the COMP channels.  
 0:  $V_{REFINT}$  scaler disabled (if SCALEN bit of COMP\_CFGR2 register is also low)  
 1:  $V_{REFINT}$  scaler enabled
- Bit 1 **BRGEN**: Scaler bridge enable  
 This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.  
 0: Scaler resistor bridge disabled (if BRGEN bit of COMP\_CFGR2 register is also low)  
 1: Scaler resistor bridge enabled  
 If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level  $V_{REF\_COMP}$  (similar to  $V_{REFINT}$ ).  
 If SCALEN and BRGEN are set, the four scaler outputs provide  $V_{REF\_COMP}$ ,  $3/4 V_{REF\_COMP}$ ,  $1/2 V_{REF\_COMP}$  and  $1/4 V_{REF\_COMP}$  levels, respectively.
- Bit 0 **EN**: COMP channel 1 enable bit  
 This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 1.  
 0: Disable  
 1: Enable

### 28.7.5 Comparator configuration register 2 (COMP\_CFGR2)

The COMP\_CFGR2 is the COMP channel 1 configuration register.

Address offset: 0x10

System reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	BLANKING[3:0]			Res.	Res.	Res.	INPSEL	Res.	INMSEL[2:0]			
rw				rw						rw		rw			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	PWRMODE[1:0]		Res.	Res.	HYST[1:0]		Res.	ITEN	Res.	WINMODE	POLARITY	SCALEN	BRGEN	EN
		rw				rw			rw		rw	rw	rw	rw	rw

Bit 31 **LOCK**: Lock bit

This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 2 configuration register COMP\_CFGR2[31:0], and COMP\_OR register

0: COMP\_CFGR2[31:0] register is read/write

1: COMP\_CFGR2[31:0] and COMP\_OR registers are read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **BLANKING[3:0]**: COMP channel 2 blanking source selection bits

These bits are set and cleared by software (only if LOCK not set). These bits select which timer output controls the COMP channel 2 output blanking.

0000: No blanking

0001: TIM1 OC5 selected as blanking source

0010: TIM2 OC3 selected as blanking source

0011: TIM3 OC3 selected as blanking source

0100: TIM3 OC4 selected as blanking source

0101: TIM8 OC5 selected as blanking source

0110: TIM15 OC1 selected as blanking source

All other values: reserved

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **INPSEL**: COMP channel 2 non-inverting input selection bit

This bit is set and cleared by software (only if LOCK not set).

0: COMP2\_INP1 (PE9)

1: COMP2\_INP2 (PE11)

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **INMSEL[2:0]**: COMP channel 2 inverting input selection field

These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 2.

000 = 1/4 V<sub>REF\_COMP</sub>

001 = 1/2 V<sub>REF\_COMP</sub>

010 = 3/4 V<sub>REF\_COMP</sub>

011 = V<sub>REF\_COMP</sub>

100 = comp\_inm1 (DAC channel 1 output)

101 = comp\_inm2 (DAC channel 2 output)

110 = COMP2\_INM1 (PE10)

111 = COMP2\_INM2 (PE7)

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **PWRMODE[1:0]**: Power Mode of the COMP channel 2

These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 2.

- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Medium speed / medium power
- 11: Ultra low power / ultra-low-power

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **HYST[1:0]**: COMP channel 2 hysteresis selection bits

These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 2.

- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN**: COMP channel 2 interrupt enable

This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 2.

- 0: Interrupt generation disabled for COMP channel 2
- 1: Interrupt generation enabled for COMP channel 2

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WINMODE**: Window comparator mode selection bit

This bit is set and cleared by software (only if LOCK not set). This bit selects the window mode of the comparators. If set, the non-inverting input of COMP channel 2 is connected to the non-inverting input of the COMP channel 1.

Depending on the bit value, the non-inverting input of COMP channel 2 is connected to:

- 0: COMP2\_INP input selector
- 1: Non-inverting input comp1\_inp of COMP channel 1

Bit 3 **POLARITY**: COMP channel 2 polarity selection bit

This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 2 polarity.

- 0: COMP channel 2 output is not inverted
- 1: COMP channel 2 output is inverted

Bit 2 **SCALEN**: Voltage scaler enable bit

This bit is set and cleared by software (only if LOCK not set). This bit enables the  $V_{REFINT}$  scaler for the COMP channels.

- 0:  $V_{REFINT}$  scaler disabled (if SCALEN bit of COMP\_CFGR1 register is also low)
- 1:  $V_{REFINT}$  scaler enabled

Bit 1 **BRGEN**: Scaler bridge enable

This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.

- 0: Scaler resistor bridge disabled (if BRGEN bit of COMP\_CFGR1 register is also low)
- 1: Scaler resistor bridge enabled

If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level  $V_{REF\_COMP}$  (similar to  $V_{REFINT}$ ).

If SCALEN and BRGEN are set, the four scaler outputs provide  $V_{REF\_COMP}$ ,  $3/4 V_{REF\_COMP}$ ,  $1/2 V_{REF\_COMP}$  and  $1/4 V_{REF\_COMP}$  levels, respectively.

Bit 0 **EN**: COMP channel 2 enable bit

This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 2.

- 0: Disable
- 1: Enable

### 28.7.6 COMP register map

The following table summarizes the comparator registers.

**Table 223. COMP register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to [Section 2.2.2: Memory map and register boundary addresses](#) for the register boundary addresses.

## 29 Operational amplifiers (OPAMP)

### 29.1 Introduction

The devices embed two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, thus enabling any type of external interconnections. The operational amplifiers can be configured internally as a follower, as an amplifier with a non-inverting gain ranging from 2 to 16 or with inverting gain ranging from -1 to -15.

The positive input can be connected to the internal DAC.

One of the output can be connected to the internal ADC.

### 29.2 OPAMP main features

- Rail-to-rail input and output voltage range
- Low input bias current (down to 1 nA)
- Low input offset voltage (1.5 mV after calibration, 10 mV with factory calibration)
- 7 MHz gain bandwidth
- High-speed mode to achieve a better slew rate

*Note:* Refer to the product datasheet for detailed OPAMP characteristics.

### 29.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are two functional modes, the high-speed mode and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in [Section 29.3.3: Signal routing](#).

#### 29.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need to have read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in [Section 8.7.43: RCC APB1 Clock Register \(RCC\\_APB1LENR\)](#)).

The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations should be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.

### 29.3.2 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three input/outputs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values for its offset calibration. See electrical characteristics section of the datasheet for factory trimming conditions, usually the temperature is 30 °C and the voltage is 3 V. The trimming values can be adjusted, see [Section 29.3.5: Calibration](#) for changing the trimming values. The default configuration uses the normal mode, which provides the standard performance. The bit OPAHSM can be set in order to switch the operational amplifier to high-speed mode for a better slew rate. Both normal and high-speed mode characteristics are defined in *Section: Electrical characteristics* of the datasheet.

As soon as the OPAEN bit in OPAMPx\_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in [Section 29.3.3: Signal routing](#) and the default connection settings can be changed.

*Note:* The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx\_MODER register.

### 29.3.3 Signal routing

The routing for the operational amplifier pins is determined by OPAMPx\_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

**Table 224. Operational amplifier possible connections**

Signal	Pin	Internal	comment
OPAMP1_VINM	PC5(INM0) PA7(INM1)	ADC1_IN9 ADC2_IN9 OPAMP1_VOUT or PGA	controlled by bits PGA_GAIN and VM_SEL.
OPAMP1_VINP	PB0	dac_out1 ADC1_IN8 ADC2_IN8 COMP1_INP	controlled by bit VP_SEL.
OPAMP1_VOUT	PC4	ADC1_IN4 ADC2_IN4 COMP1_INM7	The pin is connected when the OPAMP is enabled. The ADC input is controlled by ADC.
OPAMP2_VINM	PE8(INM0) PG1(INM1)	OPAMP2_VOUT or PGA	controlled by bits PGA_GAIN and VM_SEL.
OPAMP2_VINP	PE9	dac_out2 COMP2_INP	controlled by bit VP_SEL
OPAMP2_VOUT	PE7	COMP2_INM7	-

### 29.3.4 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

*Note:* The amplifier output pin is directly connected to the output pad to minimize the output impedance. When the amplifier is enabled, it cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the internal channel.

The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

#### Standalone mode (external gain setting mode)

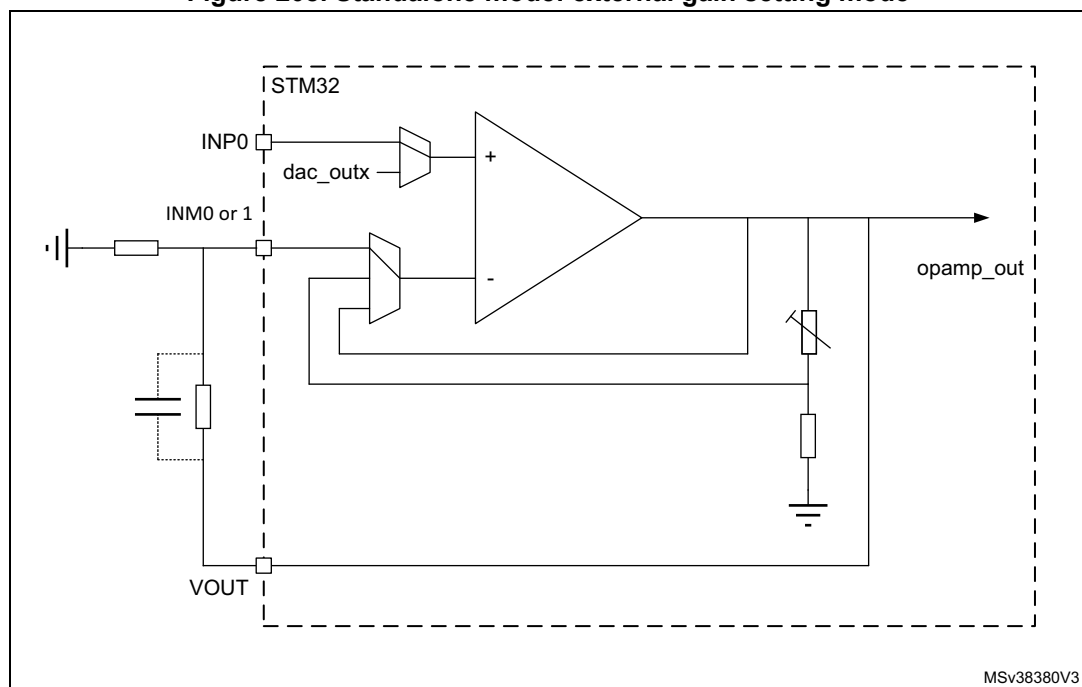

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMPx\_CSR, and the default state of GPIOx\_MODER, as soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- OPAHSM can be set to “operational amplifier high-speed” mode in order to have high slew rate.
- USERTRIM can be set to modify the trimming values for input offsets.

**Figure 208. Standalone mode: external gain setting mode**

**Follower configuration mode**

The procedure to use the OPAMP in follower mode is presented hereafter.

- configure VM\_SEL bits as “opamp\_out connected to OPAMPx\_VINM input”, 11
- configure VP\_SEL bits as “GPIO connected to OPAMPx\_VINP”, 00
- As soon as the OPAEN bit is set, the voltage on pin OPAMPx\_VINP is buffered to pin OPAMPx\_VOUT.

*Note:* The pin corresponding to OPAMPx\_VINM is free for another usage.

The signal on the OPAMP1 output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

**Figure 209. Follower configuration**

### Programmable gain amplifier mode

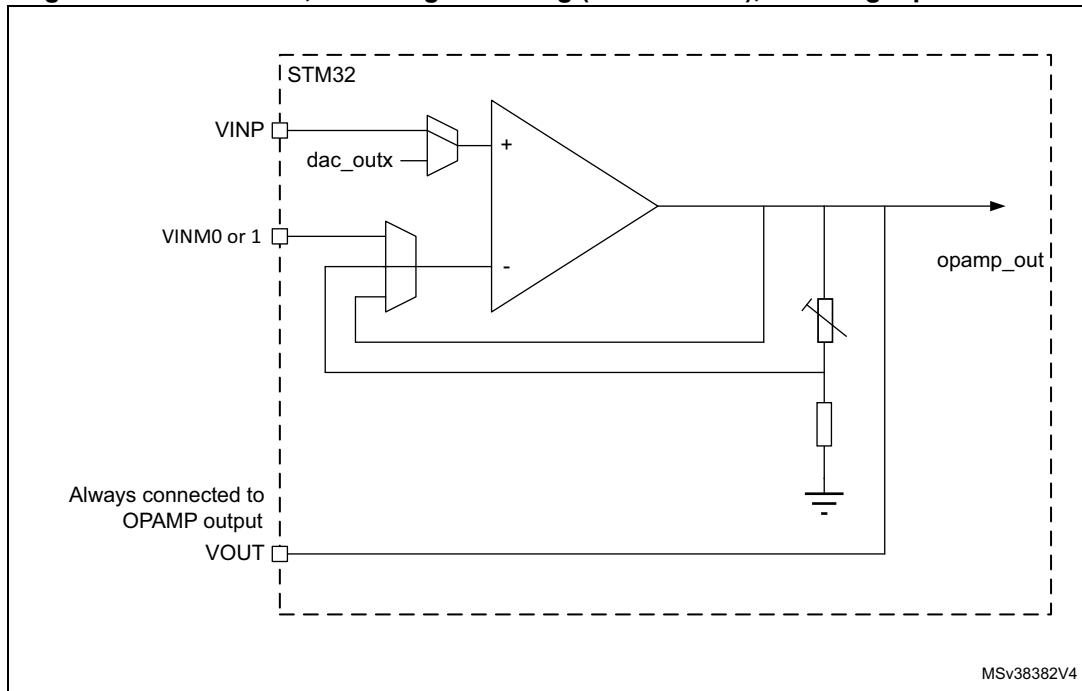

The procedure to use the OPAMP as programmable gain amplifier is presented hereafter.

- configure VM\_SEL bits as “Feedback resistor is connected to OPAMPx\_VINM input”, 10
- configure PGA\_GAIN bits as “internal Gain 2, 4, 8 or 16”, 0000 to 0011
- configure VP\_SEL bits as “GPIO connected to OPAMPx\_VINP”, 00

As soon as the OPAEN bit is set, the voltage on pin OPAMPx\_VINP is amplified by the selected gain and visible on pin OPAMPx\_VOUT.

*Note:* To avoid saturation, the input voltage should stay below  $V_{DDA}$  divided by the selected gain.

**Figure 210. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used**

### Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure VM\_SEL bits as “Feedback resistor is connected to OPAMPx\_VINM input”, 10
- configure PGA\_GAIN bits as “internal Gain 2, 4, 8 or 16 with filtering on INM0”, 0100 to 0111
- configure VP\_SEL bits as “GPIO connected to OPAMPx\_VINP”.

Any external connection on INM can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp\_outl and INM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

**Figure 211. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input used for filtering**

1. The gain depends on the cut-off frequency.

**Programmable gain amplifier, non-inverting with external bias or inverting mode**

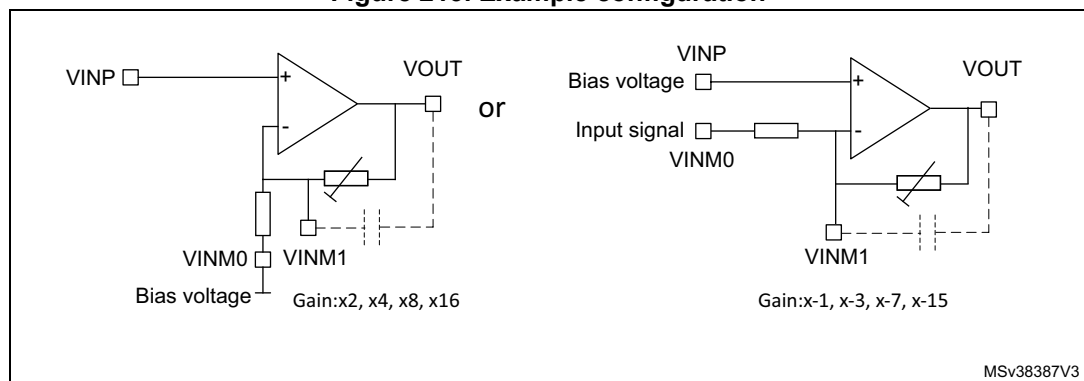

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode.

- configure VM\_SEL bits as “Feedback resistor is connected to OPAMPx\_VINM input”, 10
- configure PGA\_GAIN bits as “Inverting gain=-1,-3,-7,-15/ Non-inverting gain =2,4,8,16 with INM0”, 1000 to 1011
- configure VP\_SEL bits as “GPIO connected to OPAMPx\_VINP”.

**Figure 212. PGA mode, non-inverting gain setting (x2/x4/x8/x16) or inverting gain setting (x-1/x-3/x-7/x-15)**

**Figure 213. Example configuration**

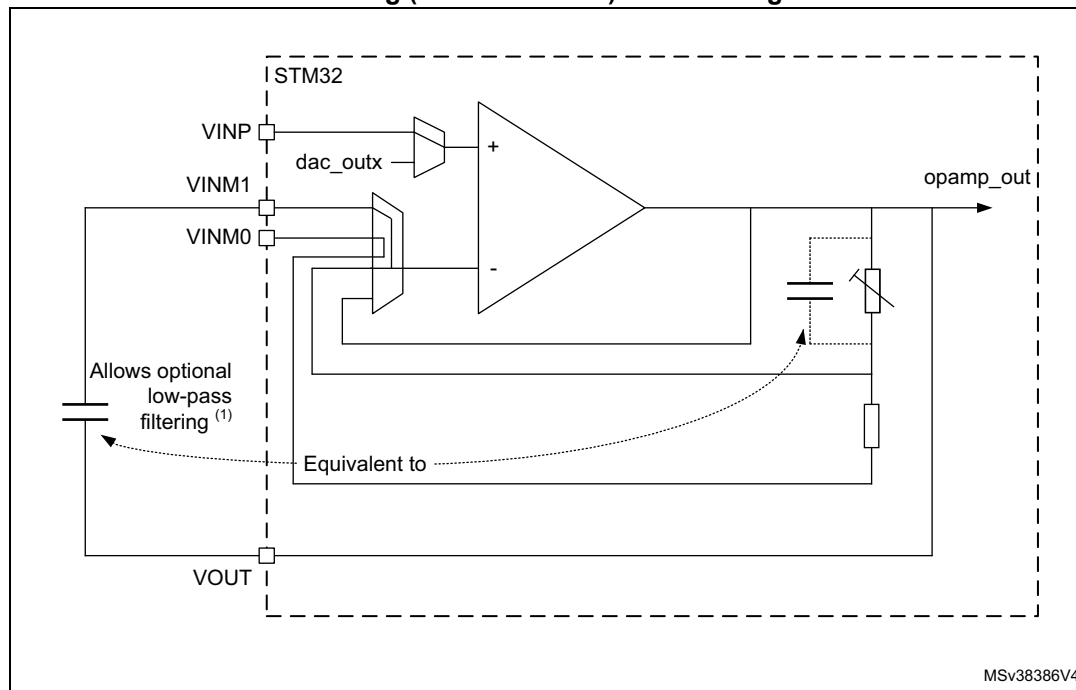

**Programmable gain amplifier, non-inverting with external bias or inverting mode with filtering**

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode with filtering

- configure VM\_SEL bits as “Feedback resistor is connected to OPAMPx\_VINM input”, 10
- configure PGA\_GAIN bits as “Inverting gain=-1,-3,-7,-15/ Non-inverting gain =2,4,8,16 with INM0, INM1 node for filtering”, 1100 to 1111
- configure VP\_SEL bits as “GPIO connected to OPAMPx\_VINP”.

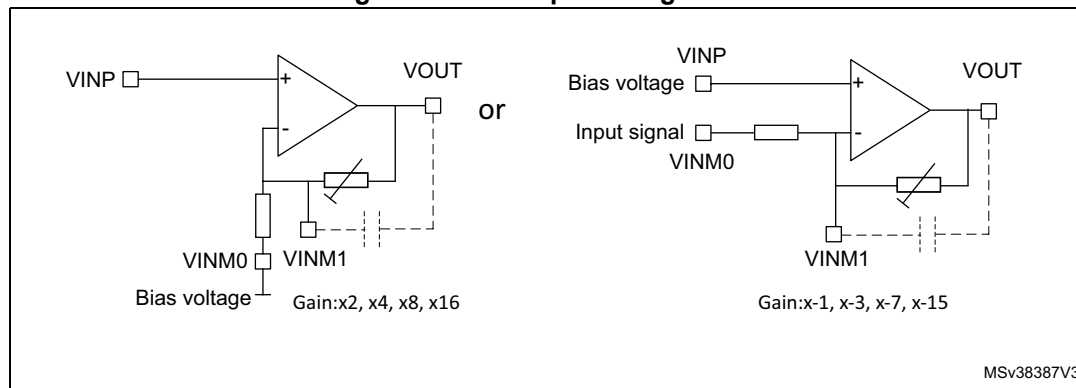

Any external connection on VM1 can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp\_out and VM1 for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

**Figure 214. PGA mode, non-inverting gain setting (x2/x4/x8/x16) or inverting gain setting (x-1/x-3/x-7/x-15) with filtering**

MSv38387V3

### 29.3.5 Calibration

The OPAMP interface continuously sends trimmed offset values to the operational amplifiers. At startup, the trimming values are initialized with the preset 'factory' trimming value.

Each operational amplifier can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for high-speed mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the input offset voltage to less than  $\pm 1.5$  mV within stable voltage and temperature conditions.

For each operational amplifier and each mode two trimming value needs to be trimmed, one for N differential pair and one for P differential pair.

There are two registers for trimming the offsets for each operational amplifiers, one for normal mode (OPAMPx\_OTR) and one high-speed mode (OPAMPx\_HSOTR). Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the 'user' values.

The user is able to switch from 'factory' values to 'user' trimmed values using the USERTRIM bit in the OPAMPx\_CSR register. This bit is reset at startup and so the 'factory' value are applied by default to the OPAMP option registers.

User is liable to change the trimming values in calibration or in functional mode.

The offset trimming registers are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the functional environment.

- Setting CALSEL to 01 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 11 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT will reflect the influence of the trimming value selected by CALSEL and OPAHSM. The software should increment the TRIMOFFSETN bits in the OPAMP control register from 0x00 to the first value that causes the CALOUT bit to change from 1 to 0 in the OPAMP register. If the CALOUT bit is reset, the offset is calibrated correctly and the corresponding trimming value must be stored. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see  $t_{OFFTRIMmax}$  delay specification in the electrical characteristics section of the datasheet).

*Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).*

**Table 225. Operating modes and calibration**

Mode	Control bits				Output	
	OPAEN	OPAHSM	CALON	CALSEL	V <sub>OUT</sub>	CALOUT flag
Normal operating mode	1	0	0	X	analog	0
High-speed mode	1	1	0	X	analog	0
Power down	0	X	X	X	Z	0

Table 225. Operating modes and calibration (continued)

Mode	Control bits				Output	
	OPAEN	OPAHSM	CALON	CALSEL	V <sub>OUT</sub>	CALOUT flag
Offset cal N diff for normal mode	1	0	1	11	analog	X
Offset cal P diff for normal mode	1	0	1	01	analog	X
Offset cal N diff for high-speed mode	1	1	1	11	analog	X
Offset cal P diff for high-speed mode	1	1	1	01	analog	X

### Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set the OPAEN bit in OPAMPx\_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMPx\_CSR register to 1.
3. Choose a calibration mode (refer to [Table 225: Operating modes and calibration](#)). The steps 3 to 4 will have to be repeated 4 times. For the first iteration select
  - Normal mode and N differential pair
 The above calibration mode correspond to OPAHSM=0 and CALSEL=11 in the OPAMPx\_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMPx\_OTR starting from 00000b until CALOUT changes to 0 in OPAMPx\_CSR.

**Note:** *Between the write to the OPAMPx\_OTR register and the read of the CALOUT value, make sure to wait for the  $t_{OFFTRIM}^{max}$  delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.*

The commutation means that the is correctly compensated and that the corresponding trim code must be saved in the OPAMPx\_OTR register.

Repeat steps 3 to 4 for:

- Normal\_mode and P differential pair, CALSEL=01
- High-speed mode and N differential pair
- High-speed mode and P differential pair

If a mode is not used, it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

**Note:** *During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500  $\mu$ A.*

## 29.4 OPAMP low-power modes

Table 226. Effect of low-power modes on the OPAMP

Mode	Description
Sleep	No effect.
D2 Stop	No effect, OPAMP registers content is kept.
Standby	The OPAMP registers are powered down and must be re-initialized after exiting Standby.

## 29.5 OPAMP PGA gain

When OPAMP is configured as PGA mode, it can select the gain of x2,x4,x8,x16 for non-inverting mode and x-1, x-3, x-7, x-15 for inverting mode.

When OPAMP is configured as non-inverting mode, the Gain error can be refer to the product datasheet. When it is configured as inverting mode, Gain factor is defined not only the on chip feedback resistor but also the signal source output impedance. If signal source output impedance is not negligible compare to the input feedback resistance of PGA, it will create the gain error. Please refer to the PGA resistance value in the product datasheet.

## 29.6 OPAMP registers

### 29.6.1 OPAMP1 control/status register (OPAMP1\_CSR)

Address: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	CAL OUT	TST REF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	USER TRIM	PGA_GAIN	
	r	rw											rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PGA_GAIN		CALSEL		CALON	Res.	Res.	OPA HSM	Res.	VM_SEL		Res.	VP_SEL		FORCE_VP	OPAEN
rw	rw	rw	rw	rw			rw		rw	rw		rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CALOUT**: Operational amplifier calibration output

OPAMP output status flag. During the calibration mode, OPAMP is used as comparator.

0: Non-inverting < inverting

1: Non-inverting > inverting

Bit 29 **TSTREF**: OPAMP calibration reference voltage output control (reserved for test)

0: INTVREF of OPAMP is not output

1: INTVREF of OPAMP is output

Bits 28:19 Reserved, must be kept at reset value.

Bit 18 **USERTRIM**: User trimming enable

This bit allows to switch from 'factory' AOP offset trimmed values to 'user' AOP offset trimmed values

This bit is active for both mode normal and high-power.

0: 'factory' trim code used

1: 'user' trim code used

Bits 17:14 **PGA\_GAIN**: Operational amplifier Programmable amplifier gain value

0000: Non-inverting internal Gain 2, VREF- referenced

0001: Non-inverting internal Gain 4, VREF- referenced

0010: Non-inverting internal Gain 8, VREF- referenced

0011: Non-inverting internal Gain 16, VREF- referenced

0100: Non-inverting internal Gain 2 with filtering on INM0, VREF- referenced

0101: Non-inverting internal Gain 4 with filtering on INM0, VREF- referenced

0110: Non-inverting internal Gain 8 with filtering on INM0, VREF- referenced

0111: Non-inverting internal Gain 16 with filtering on INM0, VREF- referenced

1000: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias

1001: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias

1010: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias

1011: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias

1100: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias, INM1 node for filtering

1101: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias, INM1 node for filtering

1110: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias, INM1 node for filtering

1111: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias, INM1 node for filtering

Bits 13:12 **CALSEL**: Calibration selection

It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE\_VP= 1.

00: 0.033\*VDDA applied on OPAMP inputs

01: 0.1\*VDDA applied on OPAMP inputs (for PMOS calibration)

10: 0.5\*VDDA applied on OPAMP inputs

11: 0.9\*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 **CALON**: Calibration mode enabled

0: Normal mode

1: Calibration mode (all switches opened by HW)

## Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **OPAHSM**: Operational amplifier high-speed mode

The operational amplifier must be disabled to change this configuration.

0: operational amplifier in normal mode

1: operational amplifier in high-speed mode

## Bit 7 Reserved, must be kept at reset value.

Bits 6:5 **VM\_SEL**: Inverting input selection

These bits are used only when OPAMODE = 00, 01, 10 or 11.

00: INM0 connected to OPAMP INM input

01: INM1 connected to OPAMP NM input

10: Feedback resistor is connected to OPAMP INM input (PGA mode), Inverting input selection is depends on the PGA\_GAIN setting

11: opamp\_out connected to OPAMP INM input (Follower mode)

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **VP\_SEL**: Non inverted input selection

00: GPIO connected to OPAMPx\_VINP

01: dac\_outx connected to OPAMPx\_VINP

10: Reserved

11: Reserved

Bit 1 **FORCE\_VP**: Force internal reference on VP (reserved for test)

0: Normal operating mode. Non-inverting input connected to inputs.

1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable

0: operational amplifier disabled

1: operational amplifier enabled

### 29.6.2 OPAMP1 trimming register in normal mode (OPAMP1\_OTR)

Address: 0x04

Reset value: 0x0000 XXXX (factory trimmed values)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## 30 Digital filter for sigma delta modulators (DFSDM)

### 30.1 Introduction

Digital filter for sigma delta modulators (DFSDM) is a high-performance module dedicated to interface external  $\Sigma\Delta$  modulators to a microcontroller. It is featuring up to 8 external digital serial interfaces (channels) and up to 4 digital filters with flexible Sigma Delta stream digital processing options to offer up to 24-bit final ADC resolution. DFSDM also features optional parallel data stream input from internal ADC peripherals or from microcontroller memory.

An external  $\Sigma\Delta$  modulator provides digital data stream of converted analog values from the external  $\Sigma\Delta$  modulator analog input. This digital data stream is sent into a DFSDM input channel through a serial interface. DFSDM supports several standards to connect various  $\Sigma\Delta$  modulator outputs: SPI interface and Manchester coded 1-wire interface (both with adjustable parameters). DFSDM module supports the connection of up to 8 multiplexed input digital serial channels which are shared with up to 4 DFSDM modules. DFSDM module also supports alternative parallel data inputs from up to 8 internal 16-bit data channels (from internal ADCs or from microcontrollers memory).

DFSDM is converting an input data stream into a final digital data word which represents an analog input value on a  $\Sigma\Delta$  modulator analog input. The conversion is based on a configurable digital process: the digital filtering and decimation of the input serial data stream.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, length of filter, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion mode and continuous mode. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible timer triggering system can be used to control the start of conversion of DFSDM. This timing control is capable of triggering simultaneous conversions or inserting a programmable delay between conversions.

DFSDM features an analog watchdog function. Analog watchdog can be assigned to any of the input channel data stream or to final output data. Analog watchdog has its own digital filtering of input data stream to reach the required speed and resolution of watched data.

To detect short-circuit in control applications, there is a short-circuit detector. This block watches each input channel data stream for occurrence of stable data for a defined time duration (several 0's or 1's in an input data stream).

An extremes detector block watches final output data and stores maximum and minimum values from the output data values. The extremes values stored can be restarted by software.

Two power modes are supported: normal mode and stop mode.

## 30.2 DFSDM main features

- Up to 8 multiplexed input digital serial channels:
  - configurable SPI interface to connect various  $\Sigma\Delta$  modulators
  - configurable Manchester coded 1 wire interface support
  - clock output for  $\Sigma\Delta$  modulator(s)
- Alternative inputs from up to 8 internal digital parallel channels:
  - inputs with up to 16 bit resolution
  - internal sources: ADCs data or memory (CPU/DMA write) data streams
- Adjustable digital signal processing:
  - Sinc<sup>X</sup> filter: filter order/type (1..5), oversampling ratio (up to 1..1024)
  - integrator: oversampling ratio (1..256)
- Up to 24-bit output data resolution:
  - right bit-shifter on final data (0..31 bits)
- Signed output data format
- Automatic data offset correction (offset stored in register by user)
- Continuous or single conversion
- Start-of-conversion synchronization with:
  - software trigger
  - internal timers
  - external events
  - start-of-conversion synchronously with first DFSDM filter (DFSDM\_FLT0)
- Analog watchdog feature:
  - low value and high value data threshold registers
  - own configurable Sinc<sup>X</sup> digital filter (order = 1..3, oversampling ratio = 1..32)
  - input from output data register or from one or more input digital serial channels
  - continuous monitoring independently from standard conversion
- Short-circuit detector to detect saturated analog input values (bottom and top ranges):
  - up to 8-bit counter to detect 1..256 consecutive 0's or 1's on input data stream
  - monitoring continuously each channel (8 serial channel transceiver outputs)
- Break generation on analog watchdog event or short-circuit detector event
- Extremes detector:
  - store minimum and maximum values of output data values
  - refreshed by software
- DMA may be used to read the conversion data
- Interrupts: end of conversion, overrun, analog watchdog, short-circuit, channel clock absence
- “regular” or “injected” conversions:
  - “regular” conversions can be requested at any time or even in continuous mode without having any impact on the timing of “injected” conversions

### 30.3 DFSDM implementation

This section describes the configuration implemented in DFSDMx.

**Table 228. DFSDM1 implementation**

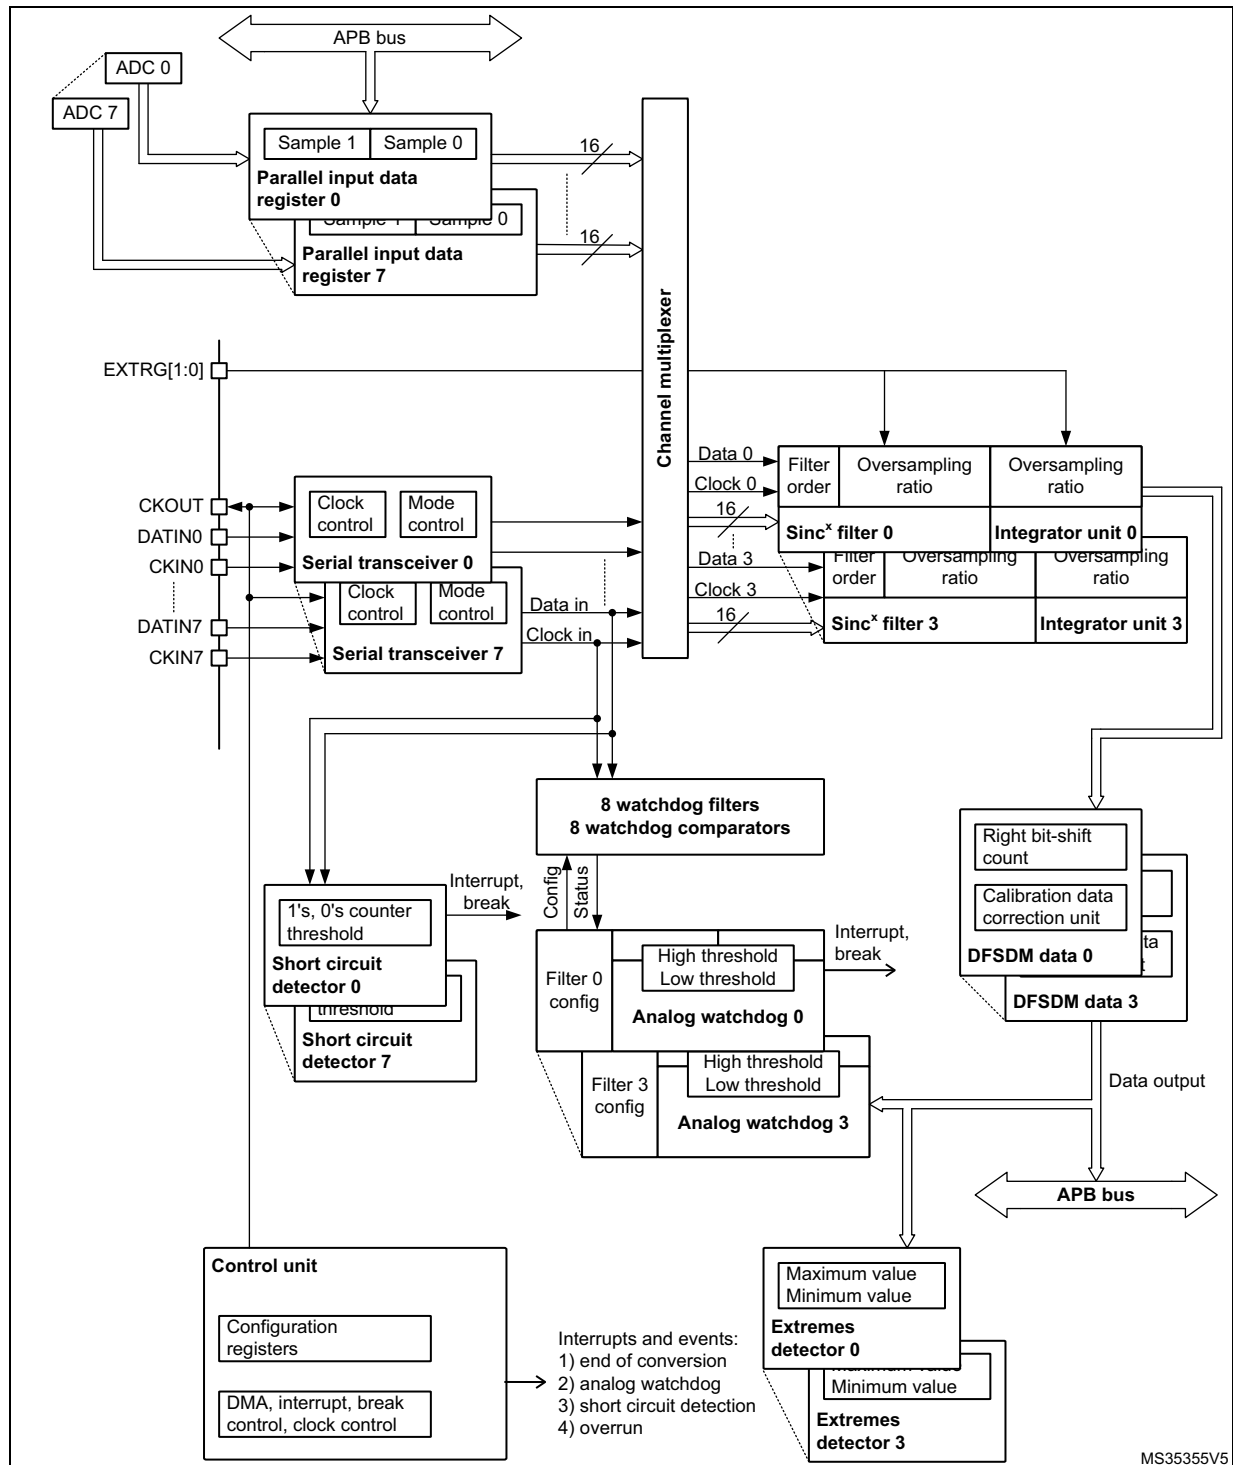

<b>DFSDM features</b>	<b>DFSDM1</b>
Number of channels	8
Number of filters	4
Input from internal ADC	X
Supported trigger sources	32
Pulses skipper	-
ID registers support	-

### 30.4 DFSDM functional description

#### 30.4.1 DFSDM block diagram

Figure 216. Single DFSDM block diagram

1. This example shows 4 DFSDM filters and 8 input channels (max. configuration).

### 30.4.2 DFSDM pins and internal signals

**Table 229. DFSDM external pins**

Name	Signal Type	Remarks
VDD	Power supply	Digital power supply.
VSS	Power supply	Digital ground power supply.
CKIN[7:0]	Clock input	Clock signal provided from external $\Sigma\Delta$ modulator. FT input.
DATIN[7:0]	Data input	Data signal provided from external $\Sigma\Delta$ modulator. FT input.
CKOUT	Clock output	Clock output to provide clock signal into external $\Sigma\Delta$ modulator.
EXTRG[1:0]	External trigger signal	Input trigger from two EXTI signals to start analog conversion (from GPIOs: EXTI11, EXTI15).

**Table 230. DFSDM internal signals**

Name	Signal Type	Remarks
dfsdm_jtrg[31:0]	Internal/external trigger signal	Input trigger from internal/external trigger sources in order to start analog conversion (from internal sources: synchronous input, from external sources: asynchronous input with synchronization). See <a href="#">Table 231</a> for details.
dfsdm_break[3:0]	break signal output	Break signals event generation from Analog watchdog or short-circuit detector
dfsdm_dma[3:0]	DMA request signal	DMA request signal from each DFSDM_FLTx (x=0..3): end of injected conversion event.
dfsdm_it[3:0]	Interrupt request signal	Interrupt signal for each DFSDM_FLTx (x=0..3)
dfsdm_dat_adc[15:0]	ADC input data	Up to 4 internal ADC data buses as parallel inputs.

**Table 231. DFSDM triggers connection**

Trigger name	Trigger source
dfsdm_jtrg0	TIM1_TRGO
dfsdm_jtrg1	TIM1_TRGO2
dfsdm_jtrg2	TIM8_TRGO
dfsdm_jtrg3	TIM8_TRGO2
dfsdm_jtrg4	TIM3_TRGO
dfsdm_jtrg5	TIM4_TRGO
dfsdm_jtrg6	TIM16_OC1

Break name	Break destination
dfsdm_break[0]	TIM15 break
dfsdm_break[1]	TIM16 break2
dfsdm_break[2]	TIM1/TIM17/TIM8 break
dfsdm_break[3]	TIM1/TIM8 break2

### 30.4.3 DFSDM reset and clocks

#### DFSDM on-off control

The DFSDM interface is globally enabled by setting DFSDMEN=1 in the DFSDM\_CH0CFGR1 register. Once DFSDM is globally enabled, all input channels (y=0..7) and digital filters DFSDM\_FLTx (x=0..3) start to work if their enable bits are set (channel enable bit CHEN in DFSDM\_CHyCFGR1 and DFSDM\_FLTx enable bit DFEN in DFSDM\_FLTxCR1).

Digital filter x DFSDM\_FLTx (x=0..3) is enabled by setting DFEN=1 in the DFSDM\_FLTxCR1 register. Once DFSDM\_FLTx is enabled (DFEN=1), both Sinc<sup>x</sup> digital filter unit and integrator unit are reinitialized.

By clearing DFEN, any conversion which may be in progress is immediately stopped and DFSDM\_FLTx is put into stop mode. All register settings remain unchanged except DFSDM\_FLTxAWSR and DFSDM\_FLTxISR (which are reset).

Channel y (y=0..7) is enabled by setting CHEN=1 in the DFSDM\_CHyCFGR1 register. Once the channel is enabled, it receives serial data from the external ΣΔ modulator or parallel internal data sources (ADCs or CPU/DMA wire from memory).

DFSDM must be globally disabled (by DFSDMEN=0 in DFSDM\_CH0CFGR1) before stopping the system clock to enter in the STOP mode of the device.

#### DFSDM clocks

The internal DFSDM clock f<sub>DFSDMCLK</sub>, which is used to drive the channel transceivers, digital processing blocks (digital filter, integrator) and next additional blocks (analog

watchdog, short-circuit detector, extremes detector, control block) is generated by the RCC block and is derived from the system clock SYSCLK (max. up to  $f_{\text{SYSCLK}} = \text{MHz}$ ) or peripheral clock PCLK2 (see DFSDMSEL bit description in ). The DFSDM clock is automatically stopped in stop mode (if DFEN = 0 for all DFSDM\_FLT $x$ ,  $x=0..3$ ).

The DFSDM serial channel transceivers can receive an external serial clock to sample an external serial data stream. The internal DFSDM clock must be at least 4 times faster than the external serial clock if standard SPI coding is used, and 6 times faster than the external serial clock if Manchester coding is used.

DFSDM can provide one external output clock signal to drive external  $\Sigma\Delta$  modulator(s) clock input(s). It is provided on CKOUT pin. This output clock signal must be in the range specified in given device datasheet and is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM\_CH0CFGR1 register) by programmable divider in the range 2 - 256 (CKOUTDIV in DFSDM\_CH0CFGR1 register). Audio clock source is SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see ).

### 30.4.4 Serial channel transceivers

There are 8 multiplexed serial data channels which can be selected for conversion by each filter or Analog watchdog or Short-circuit detector. Those serial transceivers receive data stream from external  $\Sigma\Delta$  modulator. Data stream can be sent in SPI format or Manchester coded format (see SITP[1:0] bits in DFSDM\_CHyCFGR1 register). The channel is enabled for operation by setting CHEN=1 in DFSDM\_CHyCFGR1 register.

#### Channel inputs selection

Serial inputs (data and clock signals) from DATIN $y$  and CKIN $y$  pins can be redirected from the following channel pins. This serial input channel redirection is set by CHINSEL bit in DFSDM\_CHyCFGR1 register.

Channel redirection can be used to collect audio data from PDM (pulse density modulation) stereo microphone type. PDM stereo microphone has one data and one clock signal. Data signal provides information for both left and right audio channel (rising clock edge samples for left channel and falling clock edge samples for right channel).

Configuration of serial channels for PDM microphone input:

- PDM microphone signals (data, clock) will be connected to DFSDM input serial channel  $y$  (DATIN $y$ , CKOUT) pins.
- Channel  $y$  will be configured: CHINSEL = 0 (input from given channel pins: DATIN $y$ , CKIN $y$ ).
- Channel  $(y-1)$  (modulo 8) will be configured: CHINSEL = 1 (input from the following channel  $((y-1)+1)$  pins: DATIN $y$ , CKIN $y$ ).
- Channel  $y$ : SITP[1:0] = 0 (rising edge to strobe data) => left audio channel on channel  $y$ .
- Channel  $(y-1)$ : SITP[1:0] = 1 (falling edge to strobe data) => right audio channel on channel  $y-1$ .
- Two DFSDM filters will be assigned to channel  $y$  and channel  $(y-1)$  (to filter left and right channels from PDM microphone).

Figure 217. Input channel pins redirection

**Output clock generation**

A clock signal can be provided on CKOUT pin to drive external  $\Sigma\Delta$  modulator clock inputs. The frequency of this CKOUT signal is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM\_CH0CFGR1 register) divided by a predivider (see CKOUTDIV bits in DFSDM\_CH0CFGR1 register). If the output clock is stopped, then CKOUT signal is set to low state (output clock can be stopped by CKOUTDIV=0 in DFSDM\_CHyCFGR1 register or by DFSDMEN=0 in DFSDM\_CH0CFGR1 register). The output clock stopping is performed:

- 4 system clocks after DFSDMEN is cleared (if CKOUTSRC=0)
- 1 system clock and 3 audio clocks after DFSDMEN is cleared (if CKOUTSRC=1)

Before changing CKOUTSRC the software has to wait for CKOUT being stopped to avoid glitch on CKOUT pin. The output clock signal frequency must be in the range 0 - 20 MHz.

### SPI data input format operation

In SPI format, the data stream is sent in serial format through data and clock signals. Data signal is always provided from DATINy pin. A clock signal can be provided externally from CKINy pin or internally from a signal derived from the CKOUT signal source.

In case of external clock source selection (SPICKSEL[1:0]=0) data signal (on DATINy pin) is sampled on rising or falling clock edge (of CKINy pin) according to SITP[1:0] bits setting (in DFSDM\_CHyCFGR1 register).

Internal clock sources - see SPICKSEL[1:0] in DFSDM\_CHyCFGR1 register:

- CKOUT signal:
  - For connection to external  $\Sigma\Delta$  modulator which uses directly its clock input (from CKOUT) to generate its output serial communication clock.
  - Sampling point: on rising/falling edge according to SITP[1:0] setting.
- CKOUT/2 signal (generated on CKOUT rising edge):
  - For connection to external  $\Sigma\Delta$  modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
  - Sampling point: on each second CKOUT falling edge.
- CKOUT/2 signal (generated on CKOUT falling edge):
  - For connection to external  $\Sigma\Delta$  modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
  - Sampling point: on each second CKOUT rising edge.

*Note:* An internal clock source can only be used when the external  $\Sigma\Delta$  modulator uses CKOUT signal as a clock input (to have synchronous clock and data operation).

Internal clock source usage can save CKINy pin connection (CKINy pins can be used for other purpose).

The clock source signal frequency must be in the range 0 - 20 MHz for SPI coding and less than  $f_{DFSDMCLK}/4$ .

### Manchester coded data input format operation

In Manchester coded format, the data stream is sent in serial format through DATINy pin only. Decoded data and clock signal are recovered from serial stream after Manchester decoding. There are two possible settings of Manchester codings (see SITP[1:0] bits in DFSDM\_CHyCFGR1 register):

- signal rising edge = log 0; signal falling edge = log 1
- signal rising edge = log 1; signal falling edge = log 0

The recovered clock signal frequency for Manchester coding must be in the range 0 - 10 MHz and less than  $f_{DFSDMCLK}/6$ .

To correctly receive Manchester coded data, the CKOUTDIV divider (in DFSDM\_CH0CFGR1 register) must be set with respect to expected Manchester data rate according formula:

$$((CKOUTDIV + 1) \times T_{SYSCLK}) < T_{Manchester\ clock} < (2 \times CKOUTDIV \times T_{SYSCLK})$$

Figure 218. Channel transceiver timing diagrams

### Clock absence detection

Channels serial clock inputs can be checked for clock absence/presence to ensure the correct operation of conversion and error reporting. Clock absence detection can be enabled or disabled on each input channel *y* by bit CKABEN in DFSDM\_CHyCFGR1 register. If enabled, then this clock absence detection is performed continuously on a given channel. A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock error (see CKABF[7:0] in DFSDM\_FLT0ISR register and CKABEN in DFSDM\_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM\_FLT0ICR register), the clock absence flag is refreshed. Clock absence status bit CKABF[y] is set also by hardware when corresponding channel *y* is disabled (if CHEN[y] = 0 then CKABF[y] is held in set state).

When a clock absence event has occurred, the data conversion (and/or analog watchdog and short-circuit detector) provides incorrect data. The user should manage this event and discard given data while a clock absence is reported.

The clock absence feature is available only when the system clock is used for the CKOUT signal (CKOUTSRC=0 in DFSDM\_CH0CFGR1 register).

When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM\_FLT0ICR register). The software sequence concerning clock absence detection feature should be:

- Enable given channel by CHEN = 1
- Try to clear the clock absence flag (by CLRCKABF = 1) until the clock absence flag is really cleared (CKABF = 0). At this time, the transceiver is synchronized (signal clock is valid) and is able to receive data.
- Enable the clock absence feature CKABEN = 1 and the associated interrupt CKABIE = 1 to detect if the SPI clock is lost or Manchester data edges are missing.

If SPI data format is used, then the clock absence detection is based on the comparison of an external input clock with an output clock generation (CKOUT signal). The external input clock signal into the input channel must be changed at least once per 8 signal periods of CKOUT signal (which is controlled by CKOUTDIV field in DFSDM\_CH0CFGR1 register).

Figure 219. Clock absence timing diagram for SPI

If Manchester data format is used, then the clock absence means that the clock recovery is unable to perform from Manchester coded signal. For a correct clock recovery, it is first necessary to receive data with 1 to 0 or 0 to 1 transition (see Figure 221 for Manchester synchronization).

The detection of a clock absence in Manchester coding (after a first successful synchronization) is based on changes comparison of coded serial data input signal with output clock generation (CKOUT signal). There must be a voltage level change on DATINy pin during 2 periods of CKOUT signal (which is controlled by CKOUTDIV bits in DFSDM\_CH0CFGR1 register). This condition also defines the minimum data rate to be able to correctly recover the Manchester coded data and clock signals.

The maximum data rate of Manchester coded data must be less than the CKOUT signal.

So to correctly receive Manchester coded data, the CKOUTDIV divider must be set according the formula:

$$((CKOUTDIV + 1) \times T_{SYSCLK}) < T_{Manchester\ clock} < (2 \times CKOUTDIV \times T_{SYSCLK})$$

A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock recovery error (see CKABF[7:0] in DFSDM\_FLT0ISR register and CKABEN in DFSDM\_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM\_FLT0ICR register), the clock absence flag is refreshed.

Figure 220. Clock absence timing diagram for Manchester coding

### Manchester/SPI code synchronization

The Manchester coded stream must be synchronized the first time after enabling the channel (CHEN=1 in DFSDM\_CHyCFGR1 register). The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (to be able to detect valid data edge) is received. The end of the synchronization can be checked by polling CKABF[y]=0 for a given channel after it has been cleared by CLRCKABF[y] in DFSDM\_FLT0ICR, following the software sequence detailed hereafter:

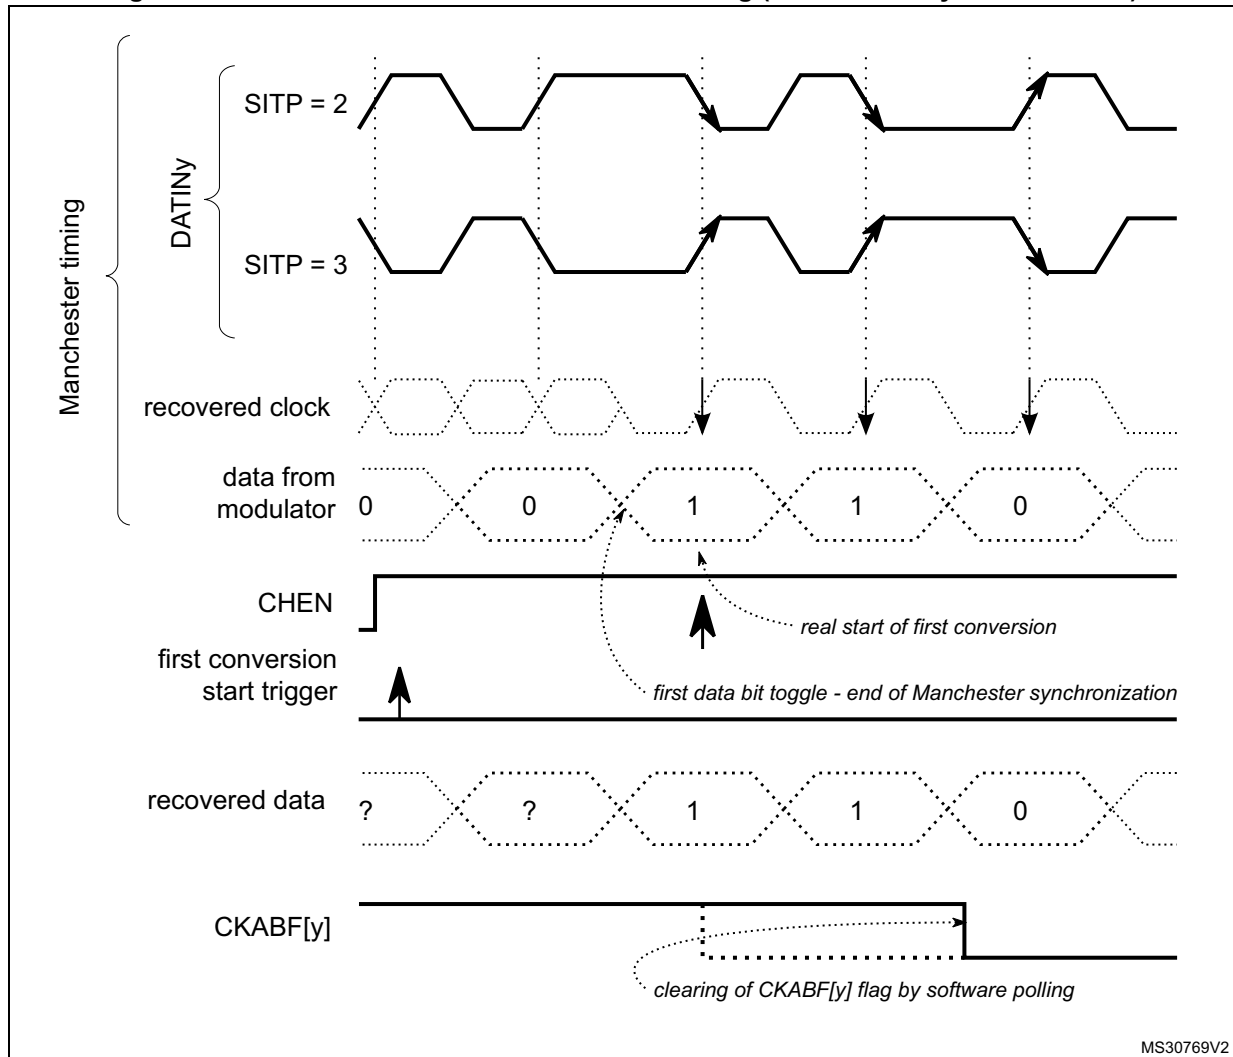

CKABF[y] flag is cleared by setting CLRCKABF[y] bit. If channel y is not yet synchronized the hardware immediately set the CKABF[y] flag. Software is then reading back the CKABF[y] flag and if it is set then perform again clearing of this flag by setting CLRCKABF[y] bit. This software sequence (polling of CKABF[y] flag) continues until CKABF[y] flag is set (signaling that Manchester stream is synchronized). To be able to synchronize/receive Manchester coded data the CKOUTDIV divider (in DFSDM\_CH0CFGR1 register) must be set with respect to expected Manchester data rate according the formula below.

$$((CKOUTDIV + 1) \times T_{SYSCLK}) < T_{Manchester\ clock} < (2 \times CKOUTDIV \times T_{SYSCLK})$$

SPI coded stream is synchronized after first detection of clock input signal (valid rising/falling edge).

*Note: When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM\_FLT0ICR register).*

Figure 221. First conversion for Manchester coding (Manchester synchronization)

MS30769V2

### External serial clock frequency measurement

The measuring of a channel serial clock input frequency provides a real data rate from an external  $\Sigma\Delta$  modulator, which is important for application purposes.

An external serial clock input frequency can be measured by a timer counting DFSDM clocks ( $f_{DFSDMCLK}$ ) during one conversion duration. The counting starts at the first input data clock after a conversion trigger (regular or injected) and finishes by last input data clock before conversion ends (end of conversion flag is set). Each conversion duration (time between first serial sample and last serial sample) is updated in counter CNVCNT[27:0] in register DFSDM\_FLTxCNVTIMR when the conversion finishes (JEOCF=1 or REOCF=1). The user can then compute the data rate according to the digital filter settings (FORD, FOSR, IOSR, FAST). The external serial frequency measurement is stopped only if the filter is bypassed (FOSR=0, only integrator is active, CNVCNT[27:0]=0 in DFSDM\_FLTxCNVTIMR register).

In case of parallel data input ([Section 30.4.6: Parallel data inputs](#)) the measured frequency is the average input data rate during one conversion.

*Note:* When conversion is interrupted (e.g. by disabling/enabling the selected channel) the interruption time is also counted in CNVCNT[27:0]. Therefore it is recommended to not interrupt the conversion for correct conversion duration result.

Conversion times:

**injected conversion or regular conversion with FAST = 0 (or first conversion if FAST=1):**

for Sinc<sup>x</sup> filters (x=1..5):

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + F_{\text{ORD}}] / f_{\text{CKIN}}$$

for FastSinc filter:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * (I_{\text{OSR}} - 1 + 4) + 2] / f_{\text{CKIN}}$$

**regular conversion with FAST = 1 (except first conversion):**

for Sinc<sup>x</sup> and FastSinc filters:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * I_{\text{OSR}}] / f_{\text{CKIN}}$$

**in case if F<sub>OSR</sub> = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):**

$$t = I_{\text{OSR}} / f_{\text{CKIN}} \text{ (... but CNVCNT=0)}$$

where:

- $f_{\text{CKIN}}$  is the channel input clock frequency (on given channel CKINy pin) or input data rate (in case of parallel data input)
- $F_{\text{OSR}}$  is the filter oversampling ratio:  $F_{\text{OSR}} = \text{FOSR}[9:0] + 1$  (see DFSDM\_FLTxFCR register)
- $I_{\text{OSR}}$  is the integrator oversampling ratio:  $I_{\text{OSR}} = \text{IOSR}[7:0] + 1$  (see DFSDM\_FLTxFCR register)
- $F_{\text{ORD}}$  is the filter order:  $F_{\text{ORD}} = \text{FORD}[2:0]$  (see DFSDM\_FLTxFCR register)

### Channel offset setting

Each channel has its own offset setting (in register) which is finally subtracted from each conversion result (injected or regular) from a given channel. Offset correction is performed after the data right bit shift. The offset is stored as a 24-bit signed value in OFFSET[23:0] field in DFSDM\_CHyCFGR2 register.

### Data right bit shift

To have the result aligned to a 24-bit value, each channel defines a number of right bit shifts which will be applied on each conversion result (injected or regular) from a given channel. The data bit shift number is stored in DTRBS[4:0] bits in DFSDM\_CHyCFGR2 register.

The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained, in order to have valid 24-bit signed format of result data.

### 30.4.5 Configuring the input serial interface

The following parameters must be configured for the input serial interface:

- **Output clock predivider.** There is a programmable predivider to generate the output clock from DFSDM clock (2 - 256). It is defined by CKOUTDIV[7:0] bits in DFSDM\_CH0CFGR1 register.
- **Serial interface type and input clock phase.** Selection of SPI or Manchester coding and sampling edge of input clock. It is defined by SITP [1:0] bits in DFSDM\_CHyCFGR1 register.
- **Input clock source.** External source from CKINy pin or internal from CKOUT pin. It is defined by SPICKSEL[1:0] field in DFSDM\_CHyCFGR1 register.
- **Final data right bit-shift.** Defines the final data right bit shift to have the result aligned to a 24-bit value. It is defined by DTRBS[4:0] in DFSDM\_CHyCFGR2 register.
- **Channel offset per channel.** Defines the analog offset of a given serial channel (offset of connected external  $\Sigma\Delta$  modulator). It is defined by OFFSET[23:0] bits in DFSDM\_CHyCFGR2 register.
- **short-circuit detector and clock absence per channel enable.** To enable or disable the short-circuit detector (by SCDEN bit) and the clock absence monitoring (by CKABEN bit) on a given serial channel in register DFSDM\_CHyCFGR1.
- **Analog watchdog filter and short-circuit detector threshold settings.** To configure channel analog watchdog filter parameters and channel short-circuit detector parameters. Configurations are defined in DFSDM\_CHyAWSCDR register.

### 30.4.6 Parallel data inputs

Each input channel provides a register for 16-bit parallel data input (besides serial data input). Each 16-bit parallel input can be sourced from internal data sources only:

- internal ADC results<sup>(2)</sup>
- direct CPU/DMA writing.

The selection for using serial or parallel data input for a given channel is done by field DATMPX[1:0] of DFSDM\_CHyCFGR1 register. In DATMPX[1:0] is also defined the parallel data source: internal ADC<sup>(2)</sup> or direct write by CPU/DMA.

Each channel contains a 32-bit data input register DFSDM\_CHyDATINR in which it can be written a 16-bit data. Data are in 16-bit signed format. Those data can be used as input to the digital filter which is accepting 16-bit parallel data.

If serial data input is selected (DATMPX[1:0] = 0), the DFSDM\_CHyDATINR register is write protected.

#### Input from internal ADC<sup>(2)</sup>

In case of ADC data parallel input (DATMPX[1:0]=1) the ADC[y+1] result is assigned to channel y input (ADC1 is filling DFSDM\_CHDATIN0R register, ADC2 is filling DFSDM\_CHDATIN1R register, ... , ADC8 is filling DFSDM\_CHDATIN7R register). End of conversion event from ADC[y+1] causes update of channel y data (parallel data from ADC[y+1] are put as next sample to digital filter). Data from ADC[y+1] is written into DFSDM\_CHyDATINR register (field INDAT0[15:0]) when end of conversion event occurred.

---

2. ADC1 and ADC2 only.

The setting of data packing mode (DATPACK[1:0] in the DFSDM\_CHyCFGR1 register) has no effect in case of ADC data input.

*Note: Extension of ADC specification: in case the internal ADC is configured in interleaved mode (e.g. ADC1 together with ADC2 - see ADC specification) then each result from ADC1 or from ADC2 will come to the same 16-bit bus - to the bus of ADC1 - which is coming into DFSDM channel 0 (fixed connection). So there will be double input data rate into DFSDM channel 0 (even samples come from ADC1 and odd samples from ADC2). Channel 1 associated with ADC2 will be free.*

### Input from memory (direct CPU/DMA write)

The direct data write into DFSDM\_CHyDATINR register by CPU or DMA (DATMPX[1:0]=2) can be used as data input in order to process digital data streams from memory or peripherals.

Data can be written by CPU or DMA into DFSDM\_CHyDATINR register:

#### 1. CPU data write:

Input data are written directly by CPU into DFSDM\_CHyDATINR register.

#### 2. DMA data write:

The DMA should be configured in memory-to-memory transfer mode to transfer data from memory buffer into DFSDM\_CHyDATINR register. The destination memory address is the address of DFSDM\_CHyDATINR register. Data are transferred at DMA transfer speed from memory to DFSDM parallel input.

This DMA transfer is different from DMA used to read DFSDM conversion results. Both DMA can be used at the same time - first DMA (configured as memory-to-memory transfer) for input data writings and second DMA (configured as peripheral-to-memory transfer) for data results reading.

The accesses to DFSDM\_CHyDATINR can be either 16-bit or 32-bit wide, allowing to load respectively one or two samples in one write operation. 32-bit input data register (DFSDM\_CHyDATINR) can be filled with one or two 16-bit data samples, depending on the data packing operation mode defined in field DATPACK[1:0] of DFSDM\_CHyCFGR1 register:

#### 1. Standard mode (DATPACK[1:0]=0):

Only one sample is stored in field INDAT0[15:0] of DFSDM\_CHyDATINR register which is used as input data for channel y. The upper 16 bits (INDAT1[15:0]) are ignored and write protected. The digital filter must perform one input sampling (from INDAT0[15:0]) to empty data register after it has been filled by CPU/DMA. This mode is used together with 16-bit CPU/DMA access to DFSDM\_CHyDATINR register to load one sample per write operation.

#### 2. Interleaved mode (DATPACK[1:0]=1):

DFSDM\_CHyDATINR register is used as a two sample buffer. The first sample is stored in INDAT0[15:0] and the second sample is stored in INDAT1[15:0]. The digital filter must perform two input samplings from channel y to empty DFSDM\_CHyDATINR register. This mode is used together with 32-bit CPU/DMA access to DFSDM\_CHyDATINR register to load two samples per write operation.

#### 3. Dual mode (DATPACK[1:0]=2):

Two samples are written into DFSDM\_CHyDATINR register. The data INDAT0[15:0] is for channel y, the data in INDAT1[15:0] is for channel y+1. The data in INDAT1[15:0] is automatically copied INDAT0[15:0] of the following (y+1) channel data register

DFSDM\_CH[y+1]DATINR). The digital filters must perform two samplings - one from channel y and one from channel (y+1) - in order to empty DFSDM\_CHyDATINR registers.

Dual mode setting (DATPACK[1:0]=2) is available only on even channel numbers (y = 0, 2, 4, 6). If odd channel (y = 1, 3, 5, 7) is set to Dual mode then both INDAT0[15:0] and INDAT1[15:0] parts are write protected for this channel. If even channel is set to Dual mode then the following odd channel must be set into Standard mode (DATPACK[1:0]=0) for correct cooperation with even channels.

See [Figure 222](#) for DFSDM\_CHyDATINR registers data modes and assignments of data samples to channels.

**Figure 222. DFSDM\_CHyDATINR registers operation modes and assignment**

Standard mode		Interleaved mode		Dual mode		
31	16 15 0	31	16 15 0	31	16 15 0	
Unused	Ch0 (sample 0)	Ch0 (sample 1) Ch0 (sample 0)		Ch1 (sample 0) Ch0 (sample 0)		<b>y = 0</b>
Unused	Ch1 (sample 0)	Ch1 (sample 1) Ch1 (sample 0)		Unused	Ch1 (sample 0)	<b>y = 1</b>

Unused	Ch3 (sample 0)	Ch3 (sample 1) Ch3 (sample 0)		Unused	Ch3 (sample 0)	<b>y = 3</b>
Unused	Ch4 (sample 0)	Ch4 (sample 1) Ch4 (sample 0)		Ch5 (sample 0) Ch4 (sample 0)		<b>y = 4</b>
Unused	Ch5 (sample 0)	Ch5 (sample 1) Ch5 (sample 0)		Unused	Ch5 (sample 0)	<b>y = 5</b>
Unused	Ch6 (sample 0)	Ch6 (sample 1) Ch6 (sample 0)		Ch7 (sample 0) Ch6 (sample 0)		<b>y = 6</b>
Unused	Ch7 (sample 0)	Ch7 (sample 1) Ch7 (sample 0)		Unused	Ch7 (sample 0)	<b>y = 7</b>

MS35354V3

The write into DFSDM\_CHyDATINR register to load one or two samples must be performed after the selected input channel (channel y) is enabled for data collection (starting conversion for channel y). Otherwise written data are lost for next processing.

For example: for single conversion and interleaved mode, do not start writing pair of data samples into DFSDM\_CHyDATINR before the single conversion is started (any data present in the DFSDM\_CHyDATINR before starting a conversion is discarded).

### 30.4.7 Channel selection

There are 8 multiplexed channels which can be selected for conversion using the injected channel group and/or using the regular channel.

The **injected channel group** is a selection of any or all of the 8 channels. JCHG[7:0] in the DFSDM\_FLTxJCHGR register selects the channels of the injected group, where JCHG[y]=1 means that channel y is selected.

Injected conversions can operate in scan mode (JSCAN=1) or single mode (JSCAN=0). In scan mode, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first, followed immediately by the next higher channel until all the channels selected by JCHG[7:0] have been converted. In single mode (JSCAN=0), only one channel from the selected channels is converted, and the channel selection is moved to the next channel. Writing to JCHG[7:0] if JSCAN=0 resets the channel selection to the lowest selected channel.

Injected conversions can be launched by software or by a trigger. They are never interrupted by regular conversions.

The **regular channel** is a selection of just one of the 8 channels. RCH[2:0] in the DFSDM\_FLTxCR1 register indicates the selected channel.

Regular conversions can be launched only by software (not by a trigger). A sequence of continuous regular conversions is temporarily interrupted when an injected conversion is requested.

Performing a conversion on a disabled channel (CHEN=0 in DFSDM\_CHyCFGR1 register) causes that the conversion will never end - because no input data is provided (with no clock signal). In this case, it is necessary to enable a given channel (CHEN=1 in DFSDM\_CHyCFGR1 register) or to stop the conversion by DFEN=0 in DFSDM\_FLTxCR1 register.

### 30.4.8 Digital filter configuration

DFSDM contains a Sinc<sup>x</sup> type digital filter implementation. This Sinc<sup>x</sup> filter performs an input digital data stream filtering, which results in decreasing the output data rate (decimation) and increasing the output data resolution. The Sinc<sup>x</sup> digital filter is configurable in order to reach the required output data rates and required output data resolution. The configurable parameters are:

- Filter order/type: (see FORD[2:0] bits in DFSDM\_FLTxFCR register):
  - FastSinc
  - Sinc<sup>1</sup>
  - Sinc<sup>2</sup>
  - Sinc<sup>3</sup>
  - Sinc<sup>4</sup>
  - Sinc<sup>5</sup>
- Filter oversampling/decimation ratio (see FOSR[9:0] bits in DFSDM\_FLTxFCR register):
  - FOSR = 1-1024 - for FastSinc filter and Sinc<sup>x</sup> filter x = F<sub>ORD</sub> = 1..3
  - FOSR = 1-215 - for Sinc<sup>x</sup> filter x = F<sub>ORD</sub> = 4
  - FOSR = 1-73 - for Sinc<sup>x</sup> filter x = F<sub>ORD</sub> = 5

The filter has the following transfer function (impulse response in H domain):

- Sinc<sup>x</sup> filter type: 
$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^x$$
- FastSinc filter type: 
$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-(2 \cdot FOSR)})$$

Figure 223. Example: Sinc<sup>3</sup> filter response

Table 233. Filter maximum output resolution (peak data values from filter output) for some FOSR values

FOSR	Sinc <sup>1</sup>	Sinc <sup>2</sup>	FastSinc	Sinc <sup>3</sup>	Sinc <sup>4</sup>	Sinc <sup>5</sup>
x	+/- x	+/- x <sup>2</sup>	+/- 2x <sup>2</sup>	+/- x <sup>3</sup>	+/- x <sup>4</sup>	+/- x <sup>5</sup>
4	+/- 4	+/- 16	+/- 32	+/- 64	+/- 256	+/- 1024
8	+/- 8	+/- 64	+/- 128	+/- 512	+/- 4096	-
32	+/- 32	+/- 1024	+/- 2048	+/- 32768	+/- 1048576	+/- 33554432
64	+/- 64	+/- 4096	+/- 8192	+/- 262144	+/- 16777216	+/- 1073741824
128	+/- 128	+/- 16384	+/- 32768	+/- 2097152	+/- 268435456	Result can overflow on full scale input (> 32-bit signed integer)
256	+/- 256	+/- 65536	+/- 131072	+/- 16777216		
1024	+/- 1024	+/- 1048576	+/- 2097152	+/- 1073741824		

For more information about Sinc filter type properties and usage, it is recommended to study the theory about digital filters (more resources can be downloaded from internet).

### 30.4.9 Integrator unit

The integrator performs additional decimation and a resolution increase of data coming from the digital filter. The integrator simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The integrator oversampling ratio parameter defines how many data counts will be summed to one data output from the integrator. IOSR can be set in the range 1-256 (see IOSR[7:0] bits description in DFSDM\_FLTxFRCR register).

**Table 234. Integrator maximum output resolution (peak data values from integrator output) for some IOSR values and FOSR = 256 and Sinc<sup>3</sup> filter type (largest data)**

IOSR	Sinc <sup>1</sup>	Sinc <sup>2</sup>	FastSinc	Sinc <sup>3</sup>	Sinc <sup>4</sup>	Sinc <sup>5</sup>
x	+/- FOSR. x	+/- FOSR <sup>2</sup> . x	+/- 2.FOSR <sup>2</sup> . x	+/- FOSR <sup>3</sup> . x	+/- FOSR <sup>4</sup> . x	+/- FOSR <sup>5</sup> . x
4	-	-	-	+/- 67 108 864	-	-
32	-	-	-	+/- 536 870 912	-	-
128	-	-	-	+/- 2 147 483 648	-	-
256	-	-	-	+/- 2 <sup>32</sup>	-	-

### 30.4.10 Analog watchdog

The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM\_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[7:0] in DFSDM\_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM\_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM\_FLTxAWLTR register).

There are 2 options for comparing the threshold registers with the data values

- Option1: in this case, the input data are taken from final output data register (AWFSEL=0). This option is characterized by:
  - high input data resolution (up to 24-bits)
  - slow response time - inappropriate for fast response applications like overcurrent detection
  - for the comparison the final data are taken after bit shifting and offset data correction
  - final data are available only after main regular or injected conversions are performed
  - can be used in case of parallel input data source (DATMPX[1:0] ≠ 0 in DFSDM\_CHyCFGR1 register)
- Option2: in this case, the input data are taken from any serial data receivers output (AWFSEL=1). This option is characterized by:
  - input serial data are processed by dedicated analog watchdog Sinc<sup>x</sup> channel filters with configurable oversampling ratio (1..32) and filter order (1..3) (see AWFOSR[4:0] and AWFORD[1:0] bits setting in DFSDM\_CHyAWSCDR register)
  - lower resolution (up to 16-bit)
  - fast response time - appropriate for applications which require a fast response like overcurrent/overvoltage detection)
  - data are available in continuous mode independently from main regular or injected conversions activity

In case of input channels monitoring (AWFSEL=1), the data for comparison to threshold is taken from channels selected by AWDCH[7:0] field (DFSDM\_FLTxCR2 register). Each of the selected channels filter result is compared to one threshold value pair (AWHT[23:0] / AWLT[23:0]). In this case, only higher 16 bits (AWHT[23:8] / AWLT[23:8]) define the 16-bit threshold compared with the analog watchdog filter output because data coming from the analog watchdog filter is up to a 16-bit resolution. Bits AWHT[7:0] / AWLT[7:0] are not taken into comparison in this case (AWFSEL=1).

Parameters of the analog watchdog filter configuration for each input channel are set in DFSDM\_CHyAWSCDR register (filter order AWFORD[1:0] and filter oversampling ratio AWFOSR[4:0]).

Each input channel has its own comparator which compares the analog watchdog data (from analog watchdog filter) with analog watchdog threshold values (AWHT/AWLT). When several channels are selected (field AWDCH[7:0] field of DFSDM\_FLTxCR2 register), several comparison requests may be received simultaneously. In this case, the channel request with the lowest number is managed first and then continuing to higher selected channels. For each channel, the result can be recorded in a separate flag (fields AWHTF[7:0], AWLTF[7:0] of DFSDM\_FLTxAWSR register). Each channel request is executed in 8 DFSDM clock cycles. So, the bandwidth from each channel is limited to 8 DFSDM clock cycles (if AWDCH[7:0] = 0xFF). Because the maximum input channel sampling clock frequency is the DFSDM clock frequency divided by 4, the configuration AWFOSR = 0 (analog watchdog filter is bypassed) cannot be used for analog watchdog feature at this input clock speed. Therefore user must properly configure the number of watched channels and analog watchdog filter parameters with respect to input sampling clock speed and DFSDM frequency.

Analog watchdog filter data for given channel y is available for reading by firmware on field WDATA[15:0] in DFSDM\_CHyWDATR register. That analog watchdog filter data is converted continuously (if CHEN=1 in DFSDM\_CHyCFGR1 register) with the data rate given by the analog watchdog filter setting and the channel input clock frequency.

The analog watchdog filter conversion works like a regular Fast Continuous Conversion without the intergator. The number of serial samples needed for one result from analog watchdog filter output (at channel input clock frequency  $f_{CKIN}$ ):

first conversion:

for Sinc<sup>x</sup> filters (x=1..5): number of samples =  $[F_{OSR} * F_{ORD} + F_{ORD} + 1]$

for FastSinc filter: number of samples =  $[F_{OSR} * 4 + 2 + 1]$

next conversions:

for Sinc<sup>x</sup> and FastSinc filters: number of samples =  $[FOSR * IOSR]$

where:

$F_{OSR}$  ..... filter oversampling ratio:  $F_{OSR} = AWFOSR[4:0] + 1$  (see DFSDM\_CHyAWSCDR register)

$F_{ORD}$  ..... the filter order:  $F_{ORD} = AWFORD[1:0]$  (see DFSDM\_CHyAWSCDR register)

In case of output data register monitoring (AWFSEL=0), the comparison is done after a right bit shift and an offset correction of final data (see OFFSET[23:0] and DTRBS[4:0] fields in DFSDM\_CHyCFGR2 register). A comparison is performed after each injected or regular end of conversion for the channels selected by AWDCH[7:0] field (in DFSDM\_FLTxCR2 register).

The status of an analog watchdog event is signaled in DFSDM\_FLTxAWSR register where a given event is latched. AWHTF[y]=1 flag signalizes crossing AWHT[23:0] value on channel y. AWLTF[y]=1 flag signalizes crossing AWLT[23:0] value on channel y. Latched events in DFSDM\_FLTxAWSR register are cleared by writing '1' into the corresponding clearing bit CLRAWHTF[y] or CLRAWLTF[y] in DFSDM\_FLTxAWCFR register.

The global status of an analog watchdog is signaled by the AWDF flag bit in DFSDM\_FLTxISR register (it is used for the fast detection of an interrupt source). AWDF=1 signalizes that at least one watchdog occurred (AWHTF[y]=1 or AWLTF[y]=1 for at least one channel). AWDF bit is cleared when all AWHTF[7:0] and AWLTF[7:0] are cleared.

An analog watchdog event can be assigned to break output signal. There are four break outputs to be assigned to a high or low threshold crossing event (dfsdm\_break[3:0]). The break signal assignment to a given analog watchdog event is done by BKAWH[3:0] and BKAWL[3:0] fields in DFSDM\_FLTxAWHTR and DFSDM\_FLTxAWLTR register.

### 30.4.11 Short-circuit detector

The purpose of a short-circuit detector is to signalize with a very fast response time if an analog signal reached saturated values (out of full scale ranges) and remained on this value given time. This behavior can detect short-circuit or open circuit errors (e.g. overcurrent or overvoltage). An interrupt/event/break generation can be invoked.

Input data into a short-circuit detector is taken from channel transceiver outputs.

There is an upcounting counter on each input channel which is counting consecutive 0's or 1's on serial data receiver outputs. A counter is restarted if there is a change in the data stream received - 1 to 0 or 0 to 1 change of data signal. If this counter reaches a short-circuit threshold register value (SCDT[7:0] bits in DFSDM\_CHyAWSCDR register), then a short-

circuit event is invoked. Each input channel has its short-circuit detector. Any channel can be selected to be continuously monitored by setting the SCDEN bit (in DFSDM\_CHyCFGR1 register) and it has its own short-circuit detector settings (threshold value in SCDT[7:0] bits, status bit SCDF[7:0], status clearing bits CLRSCDF[7:0]). Status flag SCDF[y] is cleared also by hardware when corresponding channel y is disabled (CHEN[y] = 0).

On each channel, a short-circuit detector event can be assigned to break output signal dfsdm\_break[3:0]. There are four break outputs to be assigned to a short-circuit detector event. The break signal assignment to a given channel short-circuit detector event is done by BKSCD[3:0] field in DFSDM\_CHyAWSCDR register.

Short circuit detector cannot be used in case of parallel input data channel selection (DATMPX[1:0] ≠ 0 in DFSDM\_CHyCFGR1 register).

Four break outputs are totally available (shared with the analog watchdog function).

### 30.4.12 Extreme detector

The purpose of an extremes detector is to collect the minimum and maximum values of final output data words (peak to peak values).

If the output data word is higher than the value stored in the extremes detector maximum register (EXMAX[23:0] bits in DFSDM\_FLTxEXMAX register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMAXCH[2:0] bits (in DFSDM\_FLTxEXMAX register) .

If the output data word is lower than the value stored in the extremes detector minimum register (EXMIN[23:0] bits in DFSDM\_FLTxEXMIN register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMINCH[2:0] bits (in DFSDM\_FLTxEXMIN register).

The minimum and maximum register values can be refreshed by software (by reading given DFSDM\_FLTxEXMAX or DFSDM\_FLTxEXMIN register). After refresh, the extremes detector minimum data register DFSDM\_FLTxEXMIN is filled with 0x7FFFFFFF (maximum positive value) and the extremes detector maximum register DFSDM\_FLTxEXMAX is filled with 0x800000 (minimum negative value).

The extremes detector performs a comparison after a right bit shift and an offset data correction. For each extremes detector, the input channels to be considered into computing the extremes value are selected in EXCH[7:0] bits (in DFSDM\_FLTxCR2 register).

### 30.4.13 Data unit block

The data unit block is the last block of the whole processing path: External  $\Sigma\Delta$  modulators - Serial transceivers - Sinc filter - Integrator - Data unit block.

The output data rate depends on the serial data stream rate, and filter and integrator settings. The maximum output data rate is:

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \dots \text{FAST} = 0, \text{ Sincx filter}$$

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \dots \text{FAST} = 0, \text{ FastSinc filter}$$

or

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \dots \text{FAST} = 1$$

Maximum output data rate in case of parallel data input:

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{DATAIN\_RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \dots \text{FAST} = 0, \text{Sincx filter}$$

or

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{DATAIN\_RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \dots \text{FAST} = 0, \text{FastSinc filter}$$

or

$$\text{Datarate}[\text{samples} / \text{s}] = \frac{f_{\text{DATAIN\_RATE}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \dots \text{FAST}=1 \text{ or any filter bypass case } (F_{\text{OSR}} = 1)$$

where:  $f_{\text{DATAIN\_RATE}}$ ...input data rate from ADC or from CPU/DMA

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM\_CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM\_CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

$$F_{\text{OSR}}^{F_{\text{ORD}}} \cdot I_{\text{OSR}} \leq 2^{31} \quad \dots \text{for Sinc}^x \text{ filters, } x = 1..5$$

$$2 \cdot F_{\text{OSR}}^2 \cdot I_{\text{OSR}} \leq 2^{31} \quad \dots \text{for FastSinc filter)}$$

*Note:* In case of filter and integrator bypass ( $I_{\text{OSR}}[7:0]=0$ ,  $F_{\text{OSR}}[9:0]=0$ ), the input data rate ( $f_{\text{DATAIN\_RATE}}$ ) must be limited to be able to read all output data:

$$f_{\text{DATAIN\_RATE}} \leq f_{\text{APB}}$$

where  $f_{\text{APB}}$  is the bus frequency to which the DFSDM peripheral is connected.

### 30.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external  $\Sigma\Delta$  modulator. An external  $\Sigma\Delta$  modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A  $\Sigma\Delta$  modulator output is always assumed in a signed format (a data stream of zeros and ones from a  $\Sigma\Delta$  modulator represents values -1 and +1).

**Signed data format in registers:** Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two's complement format).

### 30.4.15 Launching conversions

**Injected conversions** can be launched using the following methods:

- Software: writing '1' to JSWSTART in the DFSDM\_FLTxCR1 register.
- Trigger: JEXTSEL[4:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDM\_FLTxCR1 register).
- Synchronous with DFSDM\_FLT0 if JSYNC=1: for DFSDM\_FLTx ( $x>0$ ), an injected conversion is automatically launched when in DFSDM\_FLT0; the injected conversion is started by software (JSWSTART=1 in DFSDM\_FLT0CR2 register). Each injected conversion in DFSDM\_FLTx ( $x>0$ ) is always executed according to its local configuration settings (JSCAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[7:0] bits in DFSDM\_FLTxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[7:0] bits in DFSDM\_FLTxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[7:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

**Regular conversions** can be launched using the following methods:

- Software: by writing '1' to RSWSTART in the DFSDM\_FLTxCR1 register.
- Synchronous with DFSDM\_FLT0 if RSYNC=1: for DFSDM\_FLTx ( $x>0$ ), a regular conversion is automatically launched when in DFSDM\_FLT0; a regular conversion is started by software (RSWSTART=1 in DFSDM\_FLT0CR2 register). Each regular conversion in DFSDM\_FLTx ( $x>0$ ) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signaled by RPEND bit in DFSDM\_FLTxRDATAR register.

### 30.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDM\_FLTxCR1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[2:0] is converted repeatedly after '1' is written to RSWSTART.

The regular conversions executing in continuous mode can be stopped by writing '0' to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM\_FLTxCR1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:

if FAST = 0 (or first conversion if FAST=1):

for Sinc<sup>X</sup> filters:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + F_{\text{ORD}}] / f_{\text{CKIN}}$$

for FastSinc filter:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * (I_{\text{OSR}} - 1 + 4) + 2] / f_{\text{CKIN}}$$

if FAST = 1 (except first conversion):

for Sinc<sup>X</sup> and FastSinc filters:

$$t = \text{CNVCNT} / f_{\text{DFSDMCLK}} = [F_{\text{OSR}} * I_{\text{OSR}}] / f_{\text{CKIN}}$$

in case  $F_{\text{OSR}} = \text{FOSR}[9:0] + 1 = 1$  (filter bypassed, only integrator active):

$$t = I_{\text{OSR}} / f_{\text{CKIN}} \text{ (... but CNVCNT=0)}$$

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM\_FLTxCR1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM\_FLTxCR1 register).

### 30.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is '1' (in the DFSDM\_FLTxISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is '1' (in the DFSDM\_FLTxISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signaled in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When

the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDM\_FLTxCR1 writes '1' to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signalized in RPEND bit.

### 30.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

## 30.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- End of injected conversion interrupt:
  - enabled by JEOCIE bit in DFSDM\_FLTxCR2 register
  - indicated in JEOCF bit in DFSDM\_FLTxISR register
  - cleared by reading DFSDM\_FLTxJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATAACH[2:0] bits in DFSDM\_FLTxJDATAR register
- End of regular conversion interrupt:
  - enabled by REOCIE bit in DFSDM\_FLTxCR2 register
  - indicated in REOCF bit in DFSDM\_FLTxISR register
  - cleared by reading DFSDM\_FLTxRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATAACH[2:0] bits in DFSDM\_FLTxRDATAR register
- Data overrun interrupt for injected conversions:
  - occurred when injected converted data were not read from DFSDM\_FLTxJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDM\_FLTxCR2 register
  - indicated in JOVRF bit in DFSDM\_FLTxISR register
  - cleared by writing '1' into CLRJOVRF bit in DFSDM\_FLTxICR register
- Data overrun interrupt for regular conversions:
  - occurred when regular converted data were not read from DFSDM\_FLTxRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDM\_FLTxCR2 register
  - indicated in ROVRF bit in DFSDM\_FLTxISR register
  - cleared by writing '1' into CLRROVRF bit in DFSDM\_FLTxICR register
- Analog watchdog interrupt:

- occurred when converted data (output data or data from analog watchdog filter - according to AWFSEL bit setting in DFSDM\_FLTxCR1 register) crosses over/under high/low thresholds in DFSDM\_FLTxAWHTR / DFSDM\_FLTxAWLTR registers
- enabled by AWDIE bit in DFSDM\_FLTxCR2 register (on selected channels AWDCH[7:0])
- indicated in AWDF bit in DFSDM\_FLTxISR register
- separate indication of high or low analog watchdog threshold error by AWHTF[7:0] and AWLTF[7:0] fields in DFSDM\_FLTxAWSR register
- cleared by writing '1' into corresponding CLRAWHTF[7:0] or CLRAWLTF[7:0] bits in DFSDM\_FLTxAWCFR register
- Short-circuit detector interrupt:
  - occurred when the number of stable data crosses over thresholds in DFSDM\_CHyAWSCDR register
  - enabled by SCDIE bit in DFSDM\_FLTxCR2 register (on channel selected by SCDEN bit in DFSDM\_CHyCFGR1 register)
  - indicated in SCDF[7:0] bits in DFSDM\_FLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  - cleared by writing '1' into the corresponding CLRSCDF[7:0] bit in DFSDM\_FLTxICR register
- Channel clock absence interrupt:
  - occurred when there is clock absence on CKINy pin (see [Clock absence detection](#) in [Section 30.4.4: Serial channel transceivers](#))
  - enabled by CKABIE bit in DFSDM\_FLTxCR2 register (on channels selected by CKABEN bit in DFSDM\_CHyCFGR1 register)
  - indicated in CKABF[y] bit in DFSDM\_FLTxISR register
  - cleared by writing '1' into CLRCKABF[y] bit in DFSDM\_FLTxICR register

**Table 235. DFSDM interrupt requests**

Interrupt event	Event flag	Event/Interrupt clearing method	Interrupt enable control bit
End of injected conversion	JEOCF	reading DFSDM_FLTxJDATAR	JEOCIE
End of regular conversion	REOCF	reading DFSDM_FLTxRDATAR	REOCIE
Injected data overrun	JOVRF	writing CLRJOVRF = 1	JOVRIE
Regular data overrun	ROVRF	writing CLRROVRF = 1	ROVRIE
Analog watchdog	AWDF, AWHTF[7:0], AWLTF[7:0]	writing CLRAWHTF[7:0] = 1 writing CLRAWLTF[7:0] = 1	AWDIE, (AWDCH[7:0])
short-circuit detector	SCDF[7:0]	writing CLRSCDF[7:0] = 1	SCDIE, (SCDEN)
Channel clock absence	CKABF[7:0]	writing CLRCKABF[7:0] = 1	CKABIE, (CKABEN)

### 30.6 DFSDM DMA transfer

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM\_FLTxCR1 register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM\_FLTxCR1 register.

*Note:* With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM\_FLTxISR register) because DMA is reading DFSDM\_FLTxJDATAR or DFSDM\_FLTxRDATAR register.

### 30.7 DFSDM channel y registers (y=0..7)

#### 30.7.1 DFSDM channel configuration y register (DFSDM\_CHyCFGR1) (y=0..7)

This register specifies the parameters used by channel y (y = 0..7).

Address offset: 0x00 + 0x20 \* y

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DFSDM EN	CKOUT SRC	Res.	Res.	Res.	Res.	Res.	Res.	CKOUTDIV[7:0]							
r/w	r/w							r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATPACK[1:0]		DATMPX[1:0]		Res.	Res.	Res.	CHIN SEL	CHEN	CKAB EN	SCDEN	Res.	SPICKSEL[1:0]		SITP[1:0]	
r/w	r/w	r/w	r/w				r/w	r/w	r/w	r/w		r/w	r/w	r/w	r/w

Bit 31 **DFSDMEN**: Global enable for DFSDM interface

0: DFSDM interface disabled

1: DFSDM interface enabled

If DFSDM interface is enabled, then it is started to operate according to enabled y channels and enabled x filters settings (CHEN bit in DFSDM\_CHyCFGR1 and DFEN bit in DFSDM\_FLTxCR1).

Data cleared by setting DFSDMEN=0:

–all registers DFSDM\_FLTxISR are set to reset state (x = 0..3)

–all registers DFSDM\_FLTxAWSR are set to reset state (x = 0..3)

*Note:* DFSDMEN is present only in DFSDM\_CH0CFGR1 register (channel y=0)

Bit 30 **CKOUTSRC**: Output serial clock source selection

0: Source for output clock is from system clock

1: Source for output clock is from audio clock

This value can be modified only when DFSDMEN=0 (in DFSDM\_CH0CFGR1 register).

*Note:* CKOUTSRC is present only in DFSDM\_CH0CFGR1 register (channel y=0)

Bits 29:24 Reserved, must be kept at reset value.

Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider

0: Output clock generation is disabled (CKOUT signal is set to low state)

1- 255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2 - 256 (Divider = CKOUTDIV+1).

CKOUTDIV also defines the threshold for a clock absence detection.

This value can only be modified when DFSDMEN=0 (in DFSDM\_CH0CFGR1 register).

If DFSDMEN=0 (in DFSDM\_CH0CFGR1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).

*Note: CKOUTDIV is present only in DFSDM\_CH0CFGR1 register (channel y=0)*

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM\_CHyDATINR register.

0: Standard: input data in DFSDM\_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM\_CHyDATINR register one sample must be read by the DFSDM filter from channel y.

1: Interleaved: input data in DFSDM\_CHyDATINR register are stored as two samples:

–first sample in INDAT0[15:0] (assigned to channel y)

–second sample INDAT1[15:0] (assigned to channel y)

To empty DFSDM\_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).

2: Dual: input data in DFSDM\_CHyDATINR register are stored as two samples:

–first sample INDAT0[15:0] (assigned to channel y)

–second sample INDAT1[15:0] (assigned to channel y+1)

To empty DFSDM\_CHyDATINR register first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2, 4, 6), for odd channel numbers (y = 1, 3, 5, 7) DFSDM\_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.

3: Reserved

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y

0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM\_CHyDATINR register is write protected.

1: Data to channel y are taken from internal analog to digital converter ADC<sub>y+1</sub> output register update as 16-bit values (if ADC<sub>y+1</sub> is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM\_CHyDATINR register.

2: Data to channel y are taken from internal DFSDM\_CHyDATINR register by direct CPU/DMA write. There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.

3: Reserved

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

*Note: DATMPX[1:0] = 1 is supported only by ADC1 and ADC2.*

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **CHINSEL**: Channel inputs selection

0: Channel inputs are taken from pins of the same channel y.

1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bit 7 **CHEN**: Channel y enable

0: Channel y disabled

1: Channel y enabled

If channel y is enabled, then serial data receiving is started according to the given channel setting.

Bit 6 **CKABEN**: Clock absence detector enable on channel y

- 0: Clock absence detector disabled on channel y
- 1: Clock absence detector enabled on channel y

Bit 5 **SCDEN**: Short-circuit detector enable on channel y

- 0: Input channel y will not be guarded by the short-circuit detector
- 1: Input channel y will be continuously guarded by the short-circuit detector

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **SPICKSEL[1:0]**: SPI clock select for channel y

- 0: clock coming from external CKINy input - sampling point according SITP[1:0]
- 1: clock coming from internal CKOUT output - sampling point according SITP[1:0]
- 2: clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.  
For connection to external  $\Sigma\Delta$  modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
- 3: clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.  
For connection to external  $\Sigma\Delta$  modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bits 1:0 **SITP[1:0]**: Serial interface type for channel y

- 00: SPI with rising edge to strobe data
  - 01: SPI with falling edge to strobe data
  - 10: Manchester coded input on DATINy pin: rising edge = logic 0, falling edge = logic 1
  - 11: Manchester coded input on DATINy pin: rising edge = logic 1, falling edge = logic 0
- This value can only be modified when CHEN=0 (in DFSDM\_CHyCFGR1 register).

### 30.7.2 DFSDM channel configuration y register (DFSDM\_CHyCFGR2) (y=0..7)

This register specifies the parameters used by channel y (y = 0..7).

Address offset: 0x04 + 0x20 \* y

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET[23:8]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFFSET[7:0]								DTRBS[4:0]					Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 **OFFSET[23:0]**: 24-bit calibration offset for channel y

For channel y, OFFSET is applied to the results of each conversion from this channel. This value is set by software.

Bits 7:3 **DTRBS[4:0]**: Data right bit-shift for channel y

0-31: Defines the shift of the data result coming from the integrator - how many bit shifts to the right will be performed to have final results. Bit-shift is performed before offset correction. The data shift is rounding the result to nearest integer value. The sign of shifted result is maintained (to have valid 24-bit signed format of result data).

This value can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bits 2:0 Reserved, must be kept at reset value.

### 30.7.3 DFSDM channel analog watchdog and short-circuit detector register (DFSDM\_CHyAWSCDR) (y=0..7)

Short-circuit detector and analog watchdog settings for channel y (y = 0..7)

Address offset: 0x08 + 0x20 \* y

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWFORD[1:0]		Res.	AWFOSR[4:0]				
								r/w	r/w		r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BKSCD[3:0]				Res.	Res.	Res.	Res.	SCDT[7:0]							
r/w	r/w	r/w	r/w					r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **AWFORD[1:0]**: Analog watchdog Sinc filter order on channel y

0: FastSinc filter type

1: Sinc<sup>1</sup> filter type

2: Sinc<sup>2</sup> filter type

3: Sinc<sup>3</sup> filter type

Sinc<sup>x</sup> filter type transfer function:

$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^x$$

FastSinc filter type transfer function:

$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-(2 \cdot FOSR)})$$

This bit can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Bit 21 Reserved, must be kept at reset value.

Bits 20:16 **AWFOSR[4:0]**: Analog watchdog filter oversampling ratio (decimation rate) on channel y

0 - 31: Defines the length of the Sinc type filter in the range 1 - 32 (AWFOSR + 1). This number is also the decimation ratio of the analog data rate.

This bit can be modified only when CHEN=0 (in DFSDM\_CHyCFGR1 register).

Note: If AWFOSR = 0 then the filter has no effect (filter bypass).

Bits 15:12 **BKSCD[3:0]**: Break signal assignment for short-circuit detector on channel y  
 BKSCD[i] = 0: Break i signal not assigned to short-circuit detector on channel y  
 BKSCD[i] = 1: Break i signal assigned to short-circuit detector on channel y

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:0 **SCDT[7:0]**: short-circuit detector threshold for channel y  
 These bits are written by software to define the threshold counter for the short-circuit detector. If this value is reached, then a short-circuit detector event occurs on a given channel.

### 30.7.4 DFSDM channel watchdog filter data register (DFSDM\_CHyWDATR) (y=0..7)

This register contains the data resulting from the analog watchdog filter associated to the input channel y (y = 0..7).

Address offset: 0x0C + 0x20 \* y

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WDATA[15:0]**: Input channel y watchdog data  
 Data converted by the analog watchdog filter for input channel y. This data is continuously converted (no trigger) for this channel, with a limited resolution (OSR=1...32/sinc order = 1...3).

### 30.7.5 DFSDM channel data input register (DFSDM\_CHyDATINR) (y=0..7)

This register contains 16-bit input data to be processed by DFSDM filter module.

Address offset: 0x10 + 0x20 \* y

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INDAT1[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INDAT0[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **INDAT0[15:0]**: Input data for channel y or channel y+1

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

INDAT0[15:0] is write protected (not used for input sample).

If DATPACK[1:0]=1 (interleaved mode)

Second channel y data sample is stored into INDAT1[15:0]. First channel y data sample is stored into INDAT0[15:0]. Both samples are read sequentially by DFSDM\_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: sample in INDAT1[15:0] is automatically copied into INDAT0[15:0] of channel (y+1).

For odd y channels: INDAT1[15:0] is write protected.

See [Section 30.4.6: Parallel data inputs](#) for more details.

INDAT0[15:1] is in the 16-bit signed format.

Bits 15:0 **INDAT0[15:0]**: Input data for channel y

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

Channel y data sample is stored into INDAT0[15:0].

If DATPACK[1:0]=1 (interleaved mode)

First channel y data sample is stored into INDAT0[15:0]. Second channel y data sample is stored into INDAT1[15:0]. Both samples are read sequentially by DFSDM\_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: Channel y data sample is stored into INDAT0[15:0].

For odd y channels: INDAT0[15:0] is write protected.

See [Section 30.4.6: Parallel data inputs](#) for more details.

INDAT0[15:0] is in the 16-bit signed format.

## 30.8 DFSDM filter x module registers (x=0..3)

### 30.8.1 DFSDM control register 1 (DFSDM\_FLTxCR1)

Address offset: 0x100 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	AWF SEL	FAST	Res.	Res.	RCH[2:0]			Res.	Res.	RDMA EN	Res.	RSYNC	RCON T	RSW START	Res.
	rw	rw			rw	rw	rw			rw		rw	rw	r0w	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	JEXTEN[1:0]		JEXTSEL[4:0]				Res.	Res.	JDMA EN	JSCAN	JSYNC	Res.	JSW START	DFEN	
	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw		r0w	rw

- Bit 31 Reserved, must be kept at reset value.
- Bit 30 **AWFSEL**: Analog watchdog fast mode select  
 0: Analog watchdog on data output value (after the digital filter). The comparison is done after offset correction and shift  
 1: Analog watchdog on channel transceivers value (after watchdog filter)
- Bit 29 **FAST**: Fast conversion mode selection for regular conversions  
 0: Fast conversion mode disabled  
 1: Fast conversion mode enabled  
 When converting a regular conversion in continuous mode, having enabled the fast mode causes each conversion (except the first) to execute faster than in standard mode. This bit has no effect on conversions which are not continuous.  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).  
 if FAST=0 (or first conversion in continuous mode if FAST=1):  

$$t = [F_{OSR} * (I_{OSR}-1 + F_{ORD}) + F_{ORD}] / f_{CKIN} \dots$$
 for Sinc<sup>x</sup> filters  

$$t = [F_{OSR} * (I_{OSR}-1 + 4) + 2] / f_{CKIN} \dots$$
 for FastSinc filter  
 if FAST=1 in continuous mode (except first conversion):  

$$t = [F_{OSR} * I_{OSR}] / f_{CKIN}$$
  
 in case if  $F_{OSR} = F_{OSR}[9:0] + 1 = 1$  (filter bypassed, active only integrator):  

$$t = I_{OSR} / f_{CKIN}$$
 (... but CNVCNT=0)  
 where:  $f_{CKIN}$  is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input.
- Bits 28:27 Reserved, must be kept at reset value.
- Bits 26:24 **RCH[2:0]**: Regular channel selection  
 0: Channel 0 is selected as the regular channel  
 1: Channel 1 is selected as the regular channel  
 ...  
 7: Channel 7 is selected as the regular channel  
 Writing these bits when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).
- Bits 23:22 Reserved, must be kept at reset value.
- Bit 21 **RDMAEN**: DMA channel enabled to read data for the regular conversion  
 0: The DMA channel is not enabled to read regular data  
 1: The DMA channel is enabled to read regular data  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).
- Bit 20 Reserved, must be kept at reset value.
- Bit 19 **RSYNC**: Launch regular conversion synchronously with DFSDM\_FLT0  
 0: Do not launch a regular conversion synchronously with DFSDM\_FLT0  
 1: Launch a regular conversion in this DFSDM\_FLTx at the very moment when a regular conversion is launched in DFSDM\_FLT0  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).
- Bit 18 **RCONT**: Continuous mode selection for regular conversions  
 0: The regular channel is converted just once for each conversion request  
 1: The regular channel is converted repeatedly after each conversion request  
 Writing '0' to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.

Bit 17 **RSWSTART**: Software start of a conversion on the regular channel  
 0: Writing '0' has no effect  
 1: Writing '1' makes a request to start a conversion on the regular channel and causes RCIP to become '1'. If RCIP=1 already, writing to RSWSTART has no effect. Writing '1' has no effect if RSYNC=1.  
 This bit is always read as '0'.

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:13 **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions  
 00: Trigger detection is disabled  
 01: Each rising edge on the selected trigger makes a request to launch an injected conversion  
 10: Each falling edge on the selected trigger makes a request to launch an injected conversion  
 11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bits 12:8 **JEXTSEL[4:0]**: Trigger signal selection for launching injected conversions  
 0x0-0x1F: Trigger inputs selected by the following table (internal or external trigger).  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).  
*Note: synchronous trigger has latency up to one  $f_{DFSDMCLK}$  clock cycle (with deterministic jitter), asynchronous trigger has latency 2-3  $f_{DFSDMCLK}$  clock cycles (with jitter up to 1 cycle).*

	DFSDM_FLT0	DFSDM_FLT1	DFSDM_FLT2	DFSDM_FLT3
0x00	dfsdm_jtrg0	dfsdm_jtrg0	dfsdm_jtrg0	dfsdm_jtrg0
0x01	dfsdm_jtrg1	dfsdm_jtrg1	dfsdm_jtrg1	dfsdm_jtrg1
...				
0x1E	dfsdm_jtrg30	dfsdm_jtrg30	dfsdm_jtrg30	dfsdm_jtrg30
0x1F	dfsdm_jtrg31	dfsdm_jtrg31	dfsdm_jtrg31	dfsdm_jtrg31

Refer to [Table 231: DFSDM triggers connection](#).

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JDMAEN**: DMA channel enabled to read data for the injected channel group  
 0: The DMA channel is not enabled to read injected data  
 1: The DMA channel is enabled to read injected data  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bit 4 **JSCAN**: Scanning conversion mode for injected conversions  
 0: One channel conversion is performed from the injected channel group and next the selected channel from this group is selected.  
 1: The series of conversions for the injected group channels is executed, starting over with the lowest selected channel.  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).  
 Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 **JSYNC**: Launch an injected conversion synchronously with the DFSDM\_FLT0 JSWSTART trigger  
 0: Do not launch an injected conversion synchronously with DFSDM\_FLT0  
 1: Launch an injected conversion in this DFSDM\_FLTx at the very moment when an injected conversion is launched in DFSDM\_FLT0 by its JSWSTART trigger  
 This bit can be modified only when DFEN=0 (DFSDM\_FLTxCR1).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **JSWSTART**: Start a conversion of the injected group of channels

0: Writing '0' has no effect.

1: Writing '1' makes a request to convert the channels in the injected conversion group, causing JCIP to become '1' at the same time. If JCIP=1 already, then writing to JSWSTART has no effect. Writing '1' has no effect if JSYNC=1.

This bit is always read as '0'.

Bit 0 **DFEN**: DFSDM\_FLTx enable

0: DFSDM\_FLTx is disabled. All conversions of given DFSDM\_FLTx are stopped immediately and all DFSDM\_FLTx functions are stopped.

1: DFSDM\_FLTx is enabled. If DFSDM\_FLTx is enabled, then DFSDM\_FLTx starts operating according to its setting.

Data which are cleared by setting DFEN=0:

–register DFSDM\_FLTxISR is set to the reset state

–register DFSDM\_FLTxAWSR is set to the reset state

### 30.8.2 DFSDM control register 2 (DFSDM\_FLTxCR2)

Address offset: 0x104 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWDCH[7:0]							
								r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXCH[7:0]								Res.	CKAB IE	SCDIE	AWDIE	ROVR IE	JOVRI E	REOC IE	JEOCI E
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w		r/w	r/w	r/w	r/w	r/w	r/w	r/w

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **AWDCH[7:0]**: Analog watchdog channel selection

These bits select the input channel to be guarded continuously by the analog watchdog

AWDCH[y] = 0: Analog watchdog is disabled on channel y

AWDCH[y] = 1: Analog watchdog is enabled on channel y

Bits 15:8 **EXCH[7:0]**: Extremes detector channel selection

These bits select the input channels to be taken by the Extremes detector

EXCH[y] = 0: Extremes detector does not accept data from channel y

EXCH[y] = 1: Extremes detector accepts data from channel y

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CKABIE**: Clock absence interrupt enable

0: Detection of channel input clock absence interrupt is disabled

1: Detection of channel input clock absence interrupt is enabled

Please see the explanation of CKABF[7:0] in DFSDM\_FLTxISR.

Note: CKABIE is present only in DFSDM\_FLT0CR2 register (filter x=0)

- Bit 5 **SCDIE**: Short-circuit detector interrupt enable
  - 0: short-circuit detector interrupt is disabled
  - 1: short-circuit detector interrupt is enabled
 Please see the explanation of SCDF[7:0] in DFSDM\_FLTxISR.  
*Note: SCDIE is present only in DFSDM\_FLT0CR2 register (filter x=0)*
  
- Bit 4 **AWDIE**: Analog watchdog interrupt enable
  - 0: Analog watchdog interrupt is disabled
  - 1: Analog watchdog interrupt is enabled
 Please see the explanation of AWDF in DFSDM\_FLTxISR.
  
- Bit 3 **ROVRIE**: Regular data overrun interrupt enable
  - 0: Regular data overrun interrupt is disabled
  - 1: Regular data overrun interrupt is enabled
 Please see the explanation of ROVRF in DFSDM\_FLTxISR.
  
- Bit 2 **JOVRIE**: Injected data overrun interrupt enable
  - 0: Injected data overrun interrupt is disabled
  - 1: Injected data overrun interrupt is enabled
 Please see the explanation of JOVRF in DFSDM\_FLTxISR.
  
- Bit 1 **REOCIE**: Regular end of conversion interrupt enable
  - 0: Regular end of conversion interrupt is disabled
  - 1: Regular end of conversion interrupt is enabled
 Please see the explanation of REOCF in DFSDM\_FLTxISR.
  
- Bit 0 **JEOCIE**: Injected end of conversion interrupt enable
  - 0: Injected end of conversion interrupt is disabled
  - 1: Injected end of conversion interrupt is enabled
 Please see the explanation of JEOCF in DFSDM\_FLTxISR.

### 30.8.3 DFSDM interrupt and status register (DFSDM\_FLTxISR)

Address offset: 0x108 + 0x80 \* x, x = 0...3

Reset value: 0x00FF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SCDF[7:0]								CKABF[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RCIP	JCIP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AWDF	ROVRF	JOVRF	REOCF	JEOCF
	r	r									r	r	r	r	r

Bits 31:24 **SCDF[7:0]**: short-circuit detector flag

SDCF[y]=0: No short-circuit detector event occurred on channel y

SDCF[y]=1: The short-circuit detector counter reaches, on channel y, the value programmed in the DFSDM\_CHyAWSCDR registers

This bit is set by hardware. It can be cleared by software using the corresponding CLRSCDF[y] bit in the DFSDM\_FLTxICR register. SCDF[y] is cleared also by hardware when CHEN[y] = 0 (given channel is disabled).

*Note: SCDF[7:0] is present only in DFSDM\_FLT0ISR register (filter x=0)*

Bits 23:16 **CKABF[7:0]**: Clock absence flag

CKABF[y]=0: Clock signal on channel y is present.

CKABF[y]=1: Clock signal on channel y is not present.

Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y]=1 state by hardware when CHEN=0 (see DFSDM\_CHyCFGR1 register). It is held at CKABF[y]=1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM\_FLTxICR register.

*Note: CKABF[7:0] is present only in DFSDM\_FLT0ISR register (filter x=0)*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RCIP**: Regular conversion in progress status

0: No request to convert the regular channel has been issued

1: The conversion of the regular channel is in progress or a request for a regular conversion is pending

A request to start a regular conversion is ignored when RCIP=1.

Bit 13 **JCIP**: Injected conversion in progress status

0: No request to convert the injected channel group (neither by software nor by trigger) has been issued

1: The conversion of the injected channel group is in progress or a request for a injected conversion is pending, due either to '1' being written to JSWSTART or to a trigger detection

A request to start an injected conversion is ignored when JCIP=1.

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **AWDF**: Analog watchdog

0: No Analog watchdog event occurred

1: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM\_FLTxAWLTR or DFSDM\_FLTxAWHTR registers.

This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[7:0] and AWLTF[7:0] in DFSDM\_FLTxAWSR register (by writing '1' into the clear bits in DFSDM\_FLTxAWCFR register).

Bit 3 **ROVRF**: Regular conversion overrun flag

0: No regular conversion overrun has occurred

1: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already '1'. RDATAR is not affected by overruns

This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM\_FLTxICR register.

- Bit 2 **JOVRF**: Injected conversion overrun flag
  - 0: No injected conversion overrun has occurred
  - 1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already '1'. JDATAR is not affected by overruns
  - This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM\_FLTxICR register.
- Bit 1 **REOCF**: End of regular conversion flag
  - 0: No regular conversion has completed
  - 1: A regular conversion has completed and its data may be read
  - This bit is set by hardware. It is cleared when the software or DMA reads DFSDM\_FLTxRDATAR.
- Bit 0 **JEOCF**: End of injected conversion flag
  - 0: No injected conversion has completed
  - 1: An injected conversion has completed and its data may be read
  - This bit is set by hardware. It is cleared when the software or DMA reads DFSDM\_FLTxJDATAR.

*Note:* For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM\_FLTxCR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.  
 All the bits of DFSDM\_FLTxISR are automatically reset when DFEN=0.

### 30.8.4 DFSDM interrupt flag clear register (DFSDM\_FLTxICR)

Address offset: 0x10C + 0x80 \* x, x = 0...3  
 Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CLRSCDF[7:0]								CLRCKABF[7:0]							
rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLR R OVRF	CLR J OVRF	Res.	Res.
												rc_w1	rc_w1		

- Bits 31:24 **CLRSCDF[7:0]**: Clear the short-circuit detector flag
  - CLRSCDF[y]=0: Writing '0' has no effect
  - CLRSCDF[y]=1: Writing '1' to position y clears the corresponding SCDF[y] bit in the DFSDM\_FLTxISR register
  - Note:* CLRSCDF[7:0] is present only in DFSDM\_FLT0ICR register (filter x=0)
- Bits 23:16 **CLRCKABF[7:0]**: Clear the clock absence flag
  - CLRCKABF[y]=0: Writing '0' has no effect
  - CLRCKABF[y]=1: Writing '1' to position y clears the corresponding CKABF[y] bit in the DFSDM\_FLTxISR register. When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y].
  - Note:* CLRCKABF[7:0] is present only in DFSDM\_FLT0ICR register (filter x=0)
- Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CLRROVRF**: Clear the regular conversion overrun flag  
 0: Writing '0' has no effect  
 1: Writing '1' clears the ROVRF bit in the DFSDM\_FLTxISR register

Bit 2 **CLRJOVRF**: Clear the injected conversion overrun flag  
 0: Writing '0' has no effect  
 1: Writing '1' clears the JOVRF bit in the DFSDM\_FLTxISR register

Bits 1:0 Reserved, must be kept at reset value.

Note: The bits of DFSDM\_FLTxICR are always read as '0'.

### 30.8.5 DFSDM injected channel group selection register (DFSDM\_FLTxJCHGR)

Address offset: 0x110 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JCHG[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **JCHG[7:0]**: Injected channel group selection  
 JCHG[y]=0: channel y is not part of the injected group  
 JCHG[y]=1: channel y is part of the injected group  
 If JSCAN=1, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first and the sequence ends at the highest selected channel.  
 If JSCAN=0, then only one channel is converted from the selected channels, and the channel selection is moved to the next channel. Writing JCHG, if JSCAN=0, resets the channel selection to the lowest selected channel.  
 At least one channel must always be selected for the injected group. Writes causing all JCHG bits to be zero are ignored.

### 30.8.6 DFSDM filter control register (DFSDM\_FLTxFCR)

Address offset: 0x114 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FORD[2:0]			Res.	Res.	Res.	FOSR[9:0]									
rw	rw	rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IOSR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **FORD[2:0]**: Sinc filter order

- 0: FastSinc filter type
- 1: Sinc<sup>1</sup> filter type
- 2: Sinc<sup>2</sup> filter type
- 3: Sinc<sup>3</sup> filter type
- 4: Sinc<sup>4</sup> filter type
- 5: Sinc<sup>5</sup> filter type
- 6-7: Reserved

Sinc<sup>x</sup> filter type transfer function: 
$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^x$$

FastSinc filter type transfer function: 
$$H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-(2 \cdot FOSR)})$$

This bit can only be modified when DFEN=0 (DFSDM\_FLTxCR1).

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:16 **FOSR[9:0]**: Sinc filter oversampling ratio (decimation rate)

0 - 1023: Defines the length of the Sinc type filter in the range 1 - 1024 (F<sub>OSR</sub> = FOSR[9:0] + 1). This number is also the decimation ratio of the output data rate from filter.

This bit can only be modified when DFEN=0 (DFSDM\_FLTxCR1)

*Note: If FOSR = 0, then the filter has no effect (filter bypass).*

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **IOSR[7:0]**: Integrator oversampling ratio (averaging length)

0 - 255: The length of the Integrator in the range 1 - 256 (IOSR + 1). Defines how many samples from Sinc filter will be summed into one output data sample from the integrator. The output data rate from the integrator will be decreased by this number (additional data decimation ratio).

This bit can only be modified when DFEN=0 (DFSDM\_FLTxCR1)

*Note: If IOSR = 0, then the Integrator has no effect (Integrator bypass).*

### 30.8.7 DFSDM data register for injected group (DFSDM\_FLTxJDATAR)

Address offset: 0x118 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JDATA[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JDATA[7:0]								Res.	Res.	Res.	Res.	Res.	JDATA[2:0]		
r	r	r	r	r	r	r	r						r	r	r

Bits 31:8 **JDATA[23:0]**: Injected group conversion data

When each conversion of a channel in the injected group finishes, its resulting data is stored in this field. The data is valid when JEOCF=1. Reading this register clears the corresponding JEOCF.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **JDATA[2:0]**: Injected channel most recently converted

When each conversion of a channel in the injected group finishes, JDATA[2:0] is updated to indicate which channel was converted. Thus, JDATA[23:0] holds the data that corresponds to the channel indicated by JDATA[2:0].

*Note:* DMA may be used to read the data from this register. Half-word accesses may be used to read only the MSBs of conversion data.  
 Reading this register also clears JEOCF in DFSDM\_FLTxISR. Thus, the firmware must not read this register if DMA is activated to read data from this register.

### 30.8.8 DFSDM data register for the regular channel (DFSDM\_FLTxRDATAR)

Address offset: 0x11C + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

Bits 31:8 **RDATAR[23:0]**: Regular channel conversion data

When each regular conversion finishes, its data is stored in this register. The data is valid when REOCF=1. Reading this register clears the corresponding REOCF.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **RPEND**: Regular channel pending data

Regular data in RDATAR[23:0] was delayed due to an injected channel trigger during the conversion

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **RDATAR[2:0]**: Regular channel most recently converted

When each regular conversion finishes, RDATAR[2:0] is updated to indicate which channel was converted (because regular channel selection RCH[2:0] in DFSDM\_FLTxCR1 register can be updated during regular conversion). Thus RDATAR[23:0] holds the data that corresponds to the channel indicated by RDATAR[2:0].

*Note:* Half-word accesses may be used to read only the MSBs of conversion data.  
 Reading this register also clears REOCF in DFSDM\_FLTxISR.

### 30.8.9 DFSDM analog watchdog high threshold register (DFSDM\_FLTxAWHTR)

Address offset: 0x120 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AWHT[23:8]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AWHT[7:0]								Res.	Res.	Res.	Res.	BKAWH[3:0]			
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w					r/w	r/w	r/w	r/w

Bits 31:8 **AWHT[23:0]**: Analog watchdog high threshold

These bits are written by software to define the high threshold for the analog watchdog.

*Note: In case channel transceivers monitor (AWFSEL=1), the higher 16 bits (AWHT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWHT[7:0] are not taken into comparison in this case.*

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **BKAWH[3:0]**: Break signal assignment to analog watchdog high threshold event

BKAWH[i] = 0: Break i signal is not assigned to an analog watchdog high threshold event

BKAWH[i] = 1: Break i signal is assigned to an analog watchdog high threshold event

### 30.8.10 DFSDM analog watchdog low threshold register (DFSDM\_FLTxAWLTR)

Address offset: 0x124 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AWLT[23:8]															
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AWLT[7:0]								Res.	Res.	Res.	Res.	BKAWL[3:0]			
r/w	r/w	r/w	r/w	r/w	r/w	r/w	r/w					r/w	r/w	r/w	r/w

Bits 31:8 **AWLT[23:0]**: Analog watchdog low threshold

These bits are written by software to define the low threshold for the analog watchdog.

*Note: In case channel transceivers monitor (AWFSEL=1), only the higher 16 bits (AWLT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWLT[7:0] are not taken into comparison in this case.*

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **BKAWL[3:0]**: Break signal assignment to analog watchdog low threshold event

BKAWL[i] = 0: Break i signal is not assigned to an analog watchdog low threshold event

BKAWL[i] = 1: Break i signal is assigned to an analog watchdog low threshold event

### 30.8.11 DFSDM analog watchdog status register (DFSDM\_FLTxAWSR)

Address offset: 0x128 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AWHTF[7:0]								AWLTF[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **AWHTF[7:0]**: Analog watchdog high threshold flag

AWHTF[y]=1 indicates a high threshold error on channel y. It is set by hardware. It can be cleared by software using the corresponding CLRAWHTF[y] bit in the DFSDM\_FLTxAWCFR register.

Bits 7:0 **AWLTF[7:0]**: Analog watchdog low threshold flag

AWLTF[y]=1 indicates a low threshold error on channel y. It is set by hardware. It can be cleared by software using the corresponding CLRAWLTF[y] bit in the DFSDM\_FLTxAWCFR register.

*Note: All the bits of DFSDM\_FLTxAWSR are automatically reset when DFEN=0.*

### 30.8.12 DFSDM analog watchdog clear flag register (DFSDM\_FLTxAWCFR)

Address offset: 0x12C + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLRAWHTF[7:0]								CLRAWLTF[7:0]							
rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **CLRAWHTF[7:0]**: Clear the analog watchdog high threshold flag  
 CLRAWHTF[y]=0: Writing '0' has no effect  
 CLRAWHTF[y]=1: Writing '1' to position y clears the corresponding AWHTF[y] bit in the DFSDM\_FLTxAWSR register

Bits 7:0 **CLRAWLTF[7:0]**: Clear the analog watchdog low threshold flag  
 CLRAWLTF[y]=0: Writing '0' has no effect  
 CLRAWLTF[y]=1: Writing '1' to position y clears the corresponding AWLTF[y] bit in the DFSDM\_FLTxAWSR register

### 30.8.13 DFSDM Extremes detector maximum register (DFSDM\_FLTxEXMAX)

Address offset: 0x130 + 0x80 \* x, x = 0...3

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EXMAX[23:8]															
r1	r0	r0	r0	r0	r0	r0	r0	r0	r0	r0	r0	r0	r0	r0	r0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXMAX[7:0]								Res.	Res.	Res.	Res.	Res.	EXMAXCH[2:0]		
r0	r0	r0	r0	r0	r0	r0	r0						r	r	r

Bits 31:8 **EXMAX[23:0]**: Extremes detector maximum value  
 These bits are set by hardware and indicate the highest value converted by DFSDM\_FLTx.  
 EXMAX[23:0] bits are reset to value (0x800000) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMAXCH[2:0]**: Extremes detector maximum data channel.  
 These bits contains information about the channel on which the data is stored into EXMAX[23:0].  
 Bits are cleared by reading of this register.

### 30.8.14 DFSDM Extremes detector minimum register (DFSDM\_FLTxEXMIN)

Address offset: 0x134 + 0x80 \* x, x = 0...3

Reset value: 0x7FFF FF00

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EXMIN[23:8]															
r0	r1	r1	r1	r1	r1	r1	r1	r1	r1	r1	r1	r1	r1	r1	r1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXMIN[7:0]								Res.	Res.	Res.	Res.	Res.	EXMINCH[2:0]		
r1	r1	r1	r1	r1	r1	r1	r1						r	r	r

Bits 31:8 **EXMIN[23:0]**: Extremes detector minimum value

These bits are set by hardware and indicate the lowest value converted by DFSDM\_FLTx. EXMIN[23:0] bits are reset to value (0x7FFFFFFF) by reading of this register.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **EXMINCH[2:0]**: Extremes detector minimum data channel

These bits contain information about the channel on which the data is stored into EXMIN[23:0]. Bits are cleared by reading of this register.

### 30.8.15 DFSDM conversion timer register (DFSDM\_FLTxCNVTIMR)

Address offset: 0x138 + 0x80 \* x, x = 0...3

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CNVCNT[27:12]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNVCNT[11:0]												Res.	Res.	Res.	Res.
r	r	r	r	r	r	r	r	r	r	r	r				

Bits 31:4 **CNVCNT[27:0]**: 28-bit timer counting conversion time  $t = CNVCNT[27:0] / f_{DFSDMCLK}$

The timer has an input clock from DFSDM clock (system clock  $f_{DFSDMCLK}$ ). Conversion time measurement is started on each conversion start and stopped when conversion finishes (interval between first and last serial sample). Only in case of filter bypass ( $FOSR[9:0] = 0$ ) is the conversion time measurement stopped and  $CNVCNT[27:0] = 0$ . The counted time is:

if  $FAST=0$  (or first conversion in continuous mode if  $FAST=1$ ):

$$t = [F_{OSR} * (I_{OSR}-1 + F_{ORD}) + F_{ORD}] / f_{CKIN} \dots \text{for Sinc}^x \text{ filters}$$

$$t = [F_{OSR} * (I_{OSR}-1 + 4) + 2] / f_{CKIN} \dots \text{for FastSinc filter}$$

if  $FAST=1$  in continuous mode (except first conversion):

$$t = [F_{OSR} * I_{OSR}] / f_{CKIN}$$

in case if  $F_{OSR} = FOSR[9:0]+1 = 1$  (filter bypassed, active only integrator):

$$CNVCNT = 0 \text{ (counting is stopped, conversion time: } t = I_{OSR} / f_{CKIN})$$

where:  $f_{CKIN}$  is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input (from internal ADC or from CPU/DMA write)

*Note: When conversion is interrupted (e.g. by disable/enable selected channel) the timer counts also this interruption time.*

Bits 3:0 Reserved, must be kept at reset value.

### 30.8.16 DFSDM register map

The following table summarizes the DFSDM registers.

**Table 236. DFSDM register map and reset values**

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
